Relaxation of Driven Piles in Florida Soils

BED25-977-05

GRIP 2025

Gray Mullins, Ph.D., P.E.

Research Assistants: Dalton Knowles, Jason Steinbach, Justin Carlisle and Andrew Ward

Project Managers: Juan Castellanos, P.E. and Rodrigo Herrera, P.E.

Background/Introduction

- Driven piles can exhibit an increase or decrease in capacity relative to end of drive conditions defined as *set-up* or *relaxation*, respectively.
- Set-up is beneficial to pile performance; relaxation is not.
- The mechanism of pile relaxation has been attributed to dilative soil conditions that cause negative pore pressure making the soils respond stronger during driving (until the pore pressure dissipates).

Pile Relaxation

- Case studies have shown restrikes have regained capacity in as little as 0.5in or as much as 7 ft.
- Large displacement required to regain capacity is likely to be caused by negative pore pressure
- Small displacements required to regain capacity could be due to concrete creep/shortening

 Creation of a database to include all information from PDA EOID and Restrikes is the primary effort (Task 2)

Problem Statement

Relaxation is the reduction in pile capacity with time. It is a phenomenon that has been observed in several projects, especially Design Build projects as a result of verification testing. There have been reported cases in which over 25% of the original measured capacity has been lost after initial pile driving. Currently the Department does not have a methodology to assist designers estimate relaxation (protocols for In-Situ testing or laboratory testing), nor a process to establish a pile driving criteria to accept piles during construction when relaxation occurs. This creates delays, extra testing and extra costs during construction, especially because the problem is typically found after pile driving begins. In most cases the issue has been resolved by additional driving until the piles reach a stable bearing layer.

Objectives

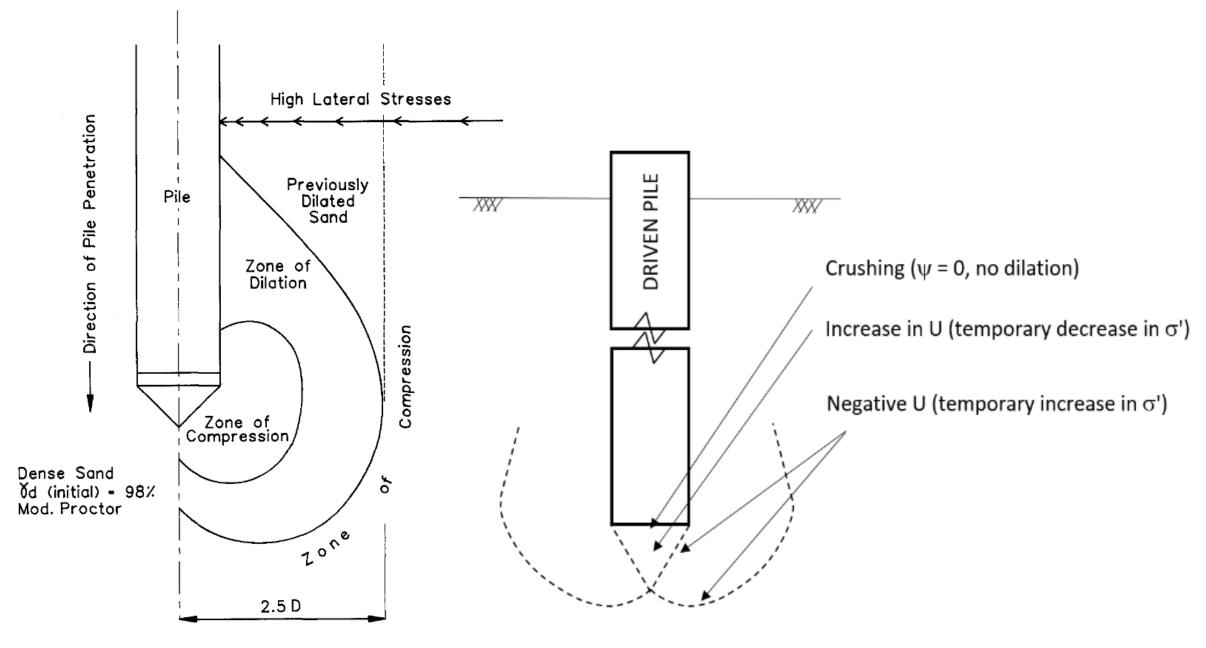

- The primary focus of this study is to document as many cases as possible from within the state of Florida where pile relaxation has been experienced.
- Determine what soil types and conditions are likely to create relaxation conditions

Revised Approach

 Collect any restrike data sets to show where both set-up and relaxation might occur

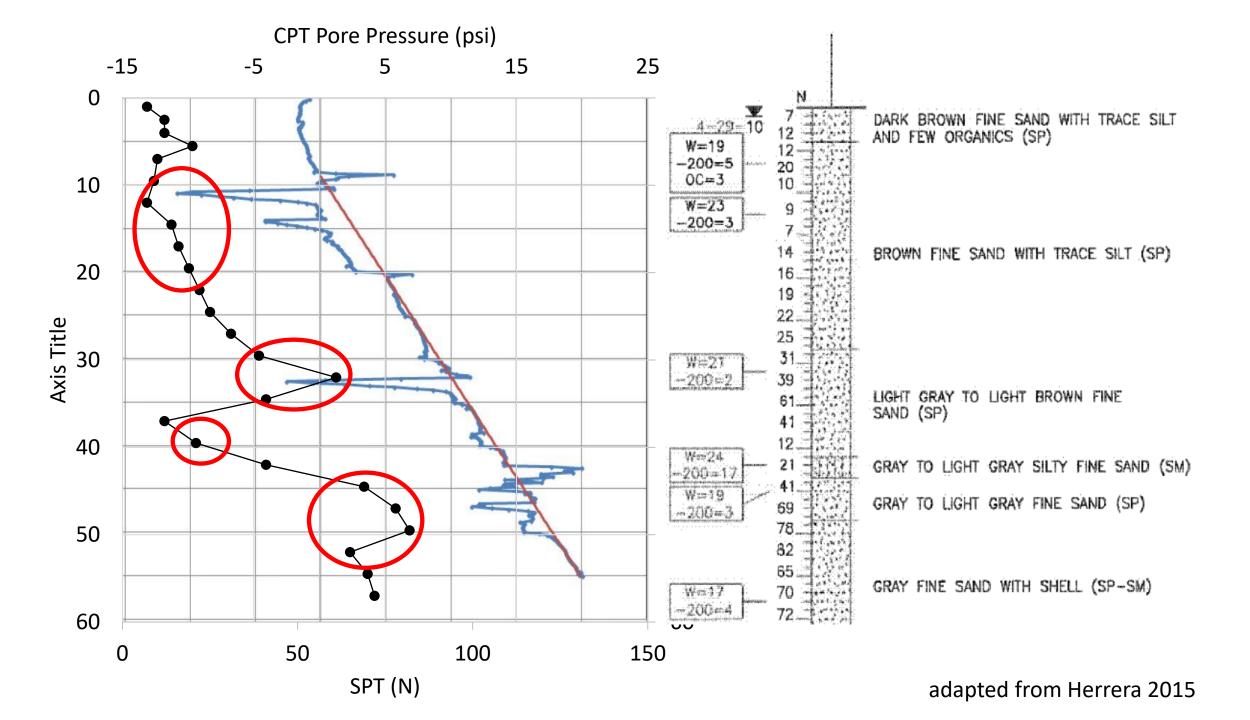

Work Tasks

- Task 1: Literature Search
- Task 2: Data Collection
- Task 3: Data Analysis
- Task 4a: Draft Final Report
- Task 4b: Closeout Meeting / Presentation
- Task 5: Final Report

York et al. 1994

Herrera et al. 2018

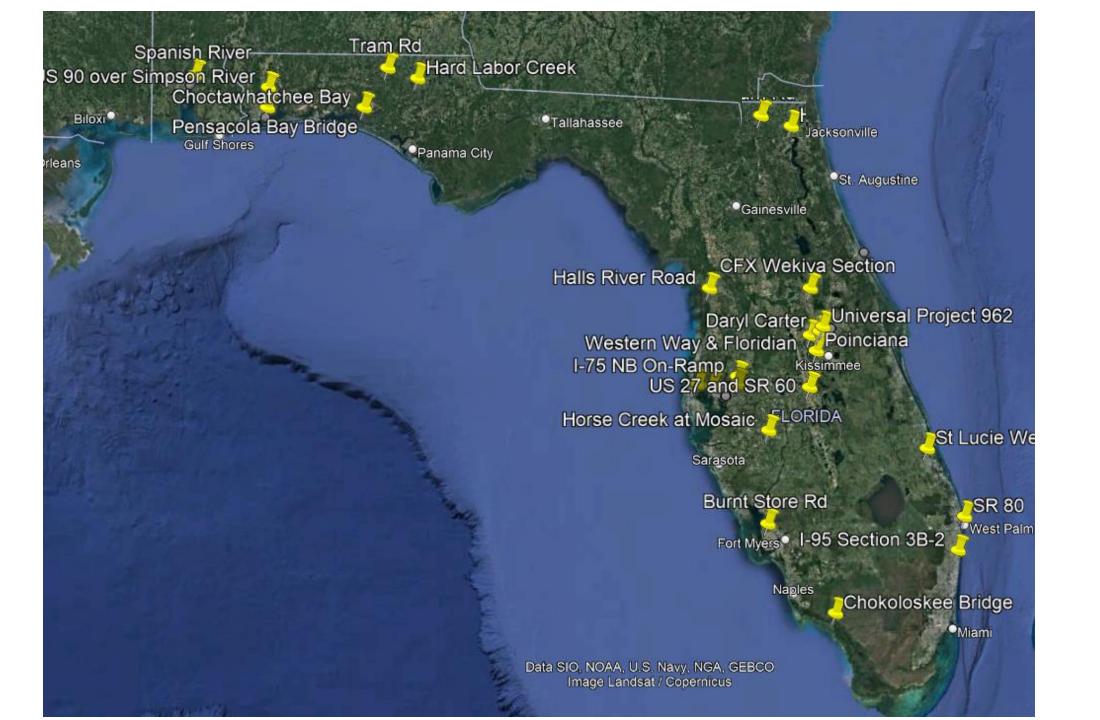

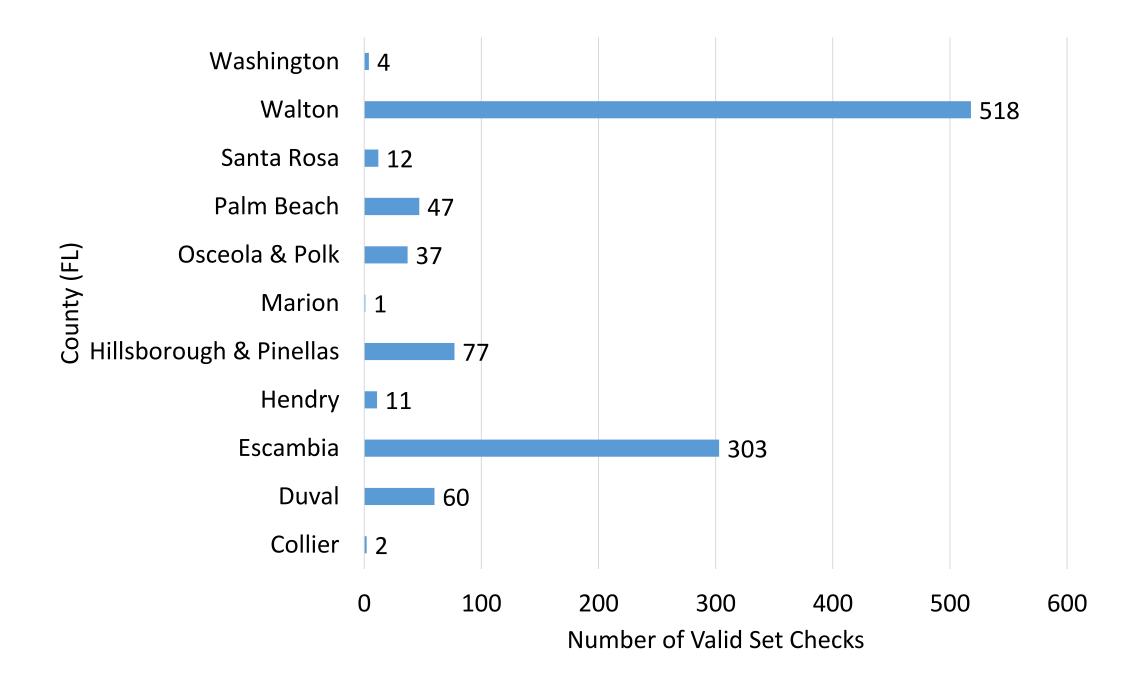

Granular Materials										
Relative Density	Safety Hammer SPT N-Value (Blow/Foot)	Automatic Hammer SPT N-Value (Blow/Foot)								
Very Loose	Less than 4	Less than 3								
Loose	4 - 10	3 – 8								
Medium Dense	10 - 30	8 – 24								
Dense	30 - 50	24 - 40								
Very Dense	Greater than 50	Greater than 40								

May dilate during pile driving

Task 2 Data Collection

- ~10,000 files review from ~6,000 piles
 - Plan sets
 - Boring logs
 - Driving logs
 - PDA reports
- Found 1111 set checks on 948 piles (EOID and Restrikes)
- 185 boring logs (some piles have same boring)
- 23 bridge sites throughout the state
- 13 counties
- 6 districts

Collected Data Types

- Pile
 - Manufacturer
 - Number
 - o Length
 - o Size
 - o Type
 - Acceptance
 - Date Cast
 - Plumbness

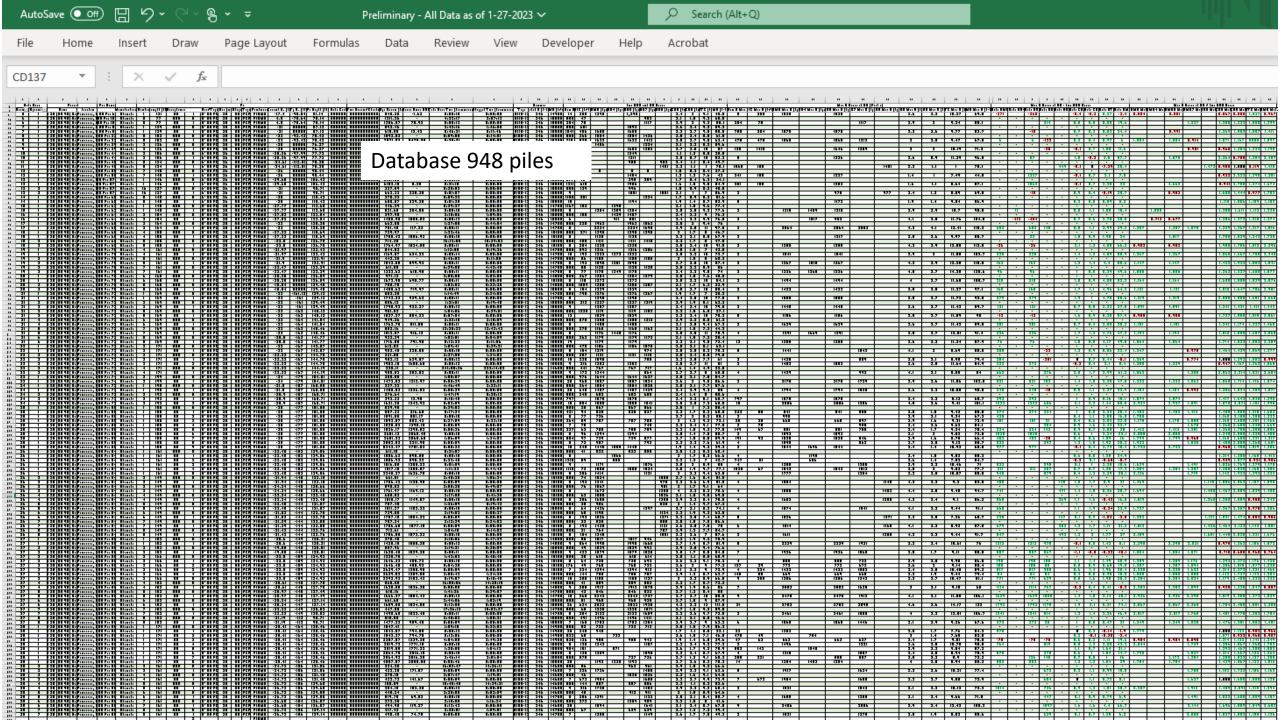

- Hammer
 - o Type
 - o Rated E (k-ft)
- Boring Logs
 - SPT Counts
 - Soil Type
 - Soil Depth

- Ground Elevation
- Tip Elevation
- Time Driven
- Time Checked
- Total Drive Time
- Total Stopped Time
- Wave Speed

Collected Data Types

- Driving Records EOD
 - Blow Count
 - BLC (bl/ft)
 - RMX Values (RX4-RX8 depending on what is available) (kips)
 - CSX (ksi)
 - CSB (ksi)
 - STK (ft)
 - **■** EMX (k-ft)

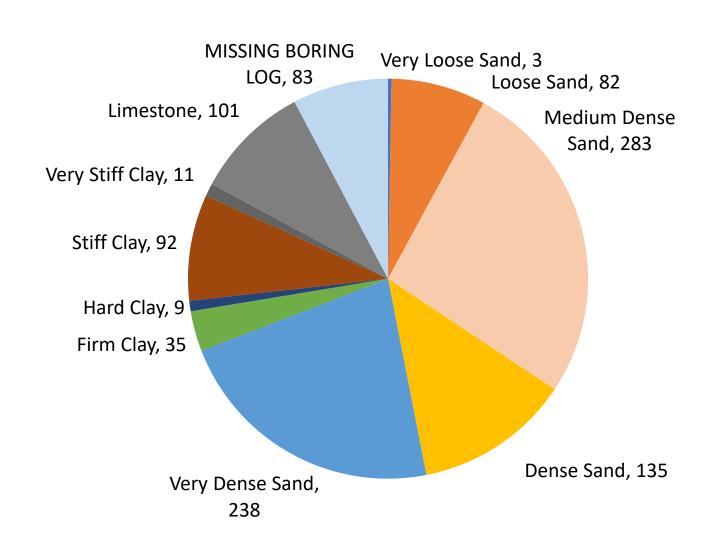

- Driving Records Restrike
 - Final and Max EMX of RS
 - Blow Count

Bearing Layer Soil Types

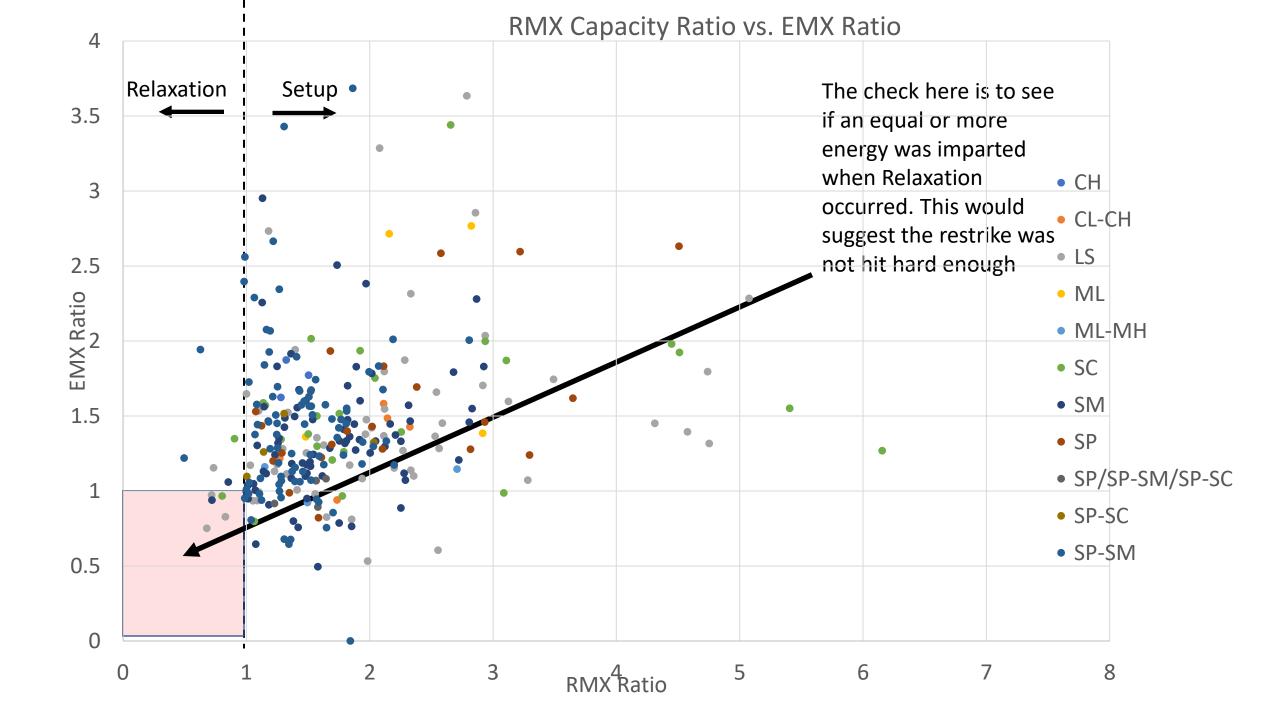

Time between Initial Drive and Restrike

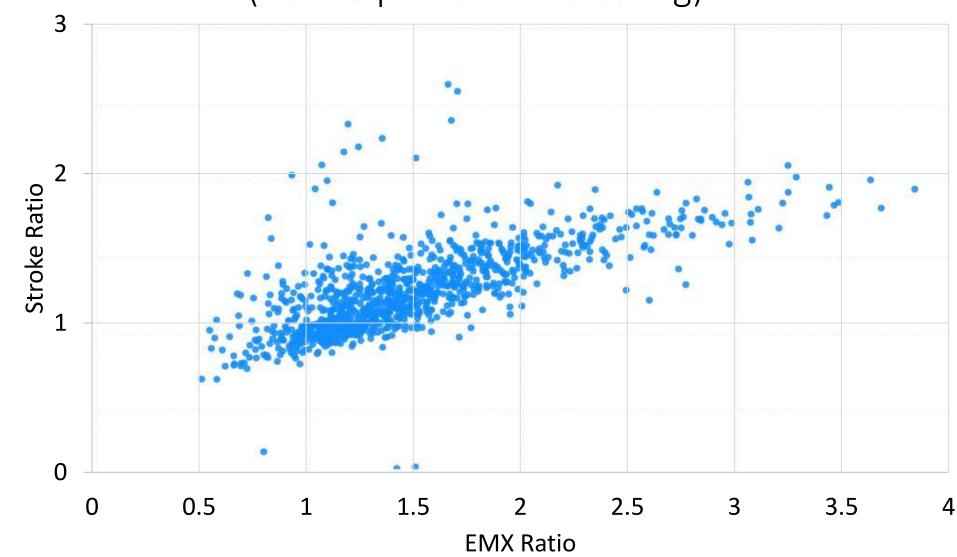

Capacity Ratio vs Wait Time

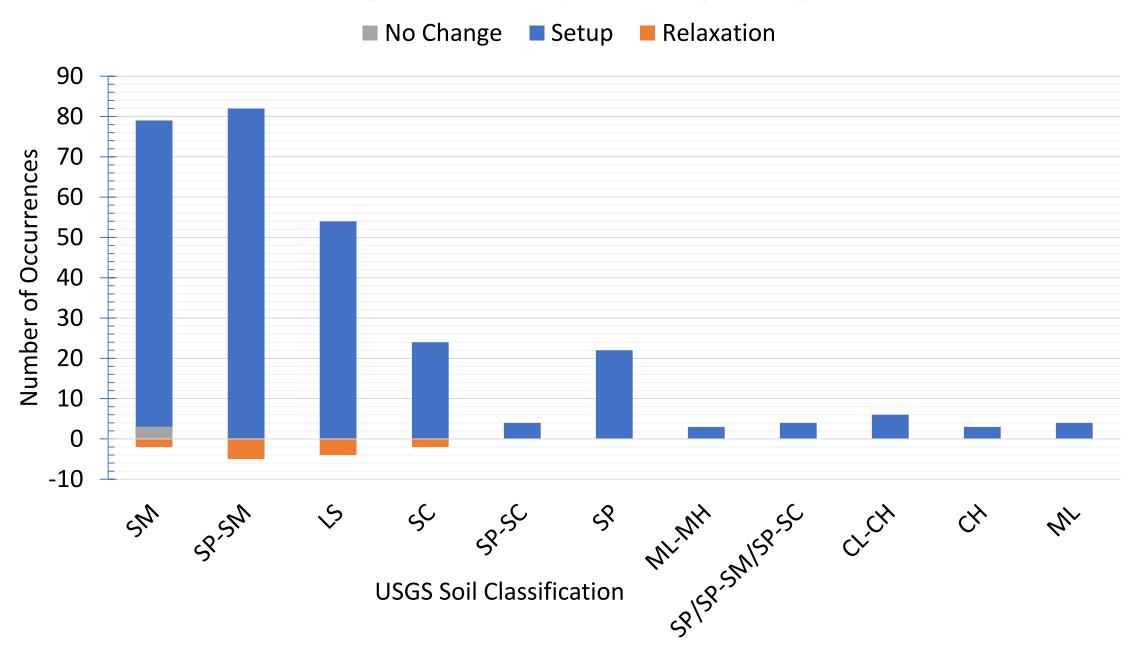

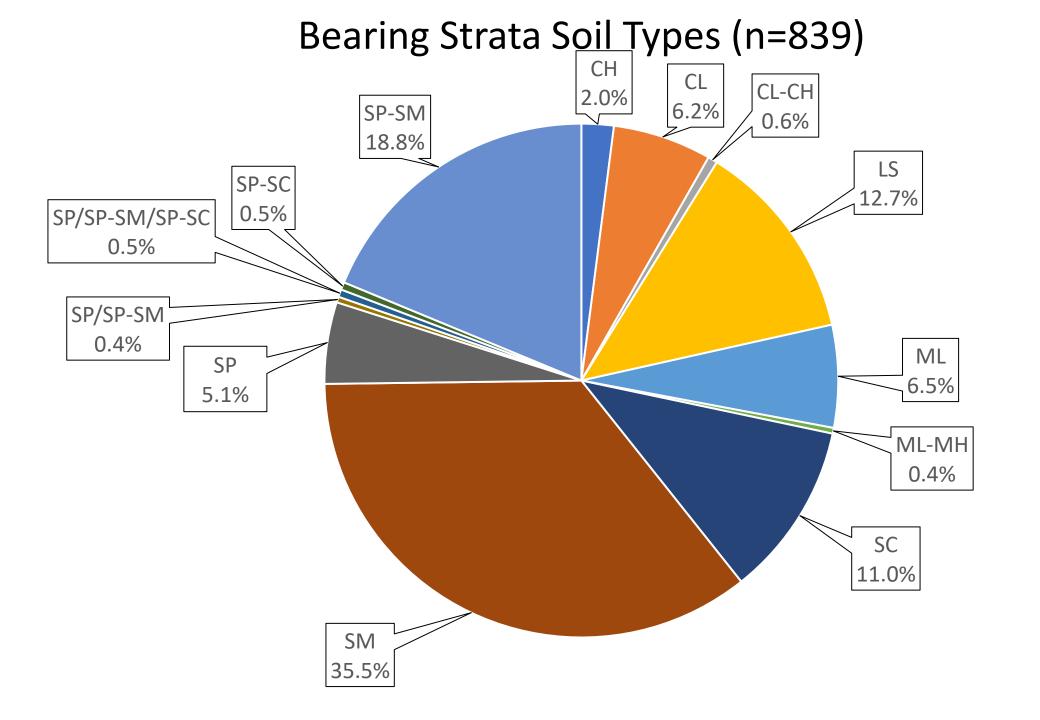

Stroke vs EMX

(not helpful but interesting)

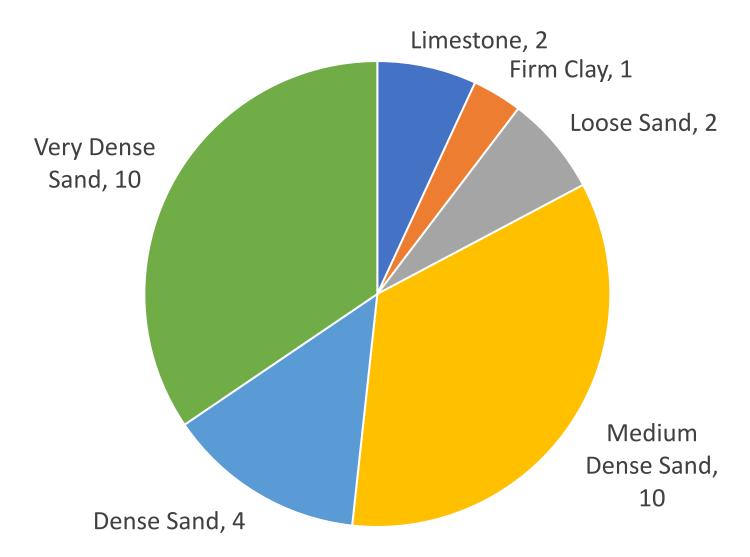

Strength Gain / Loss per Bearing Soil Type

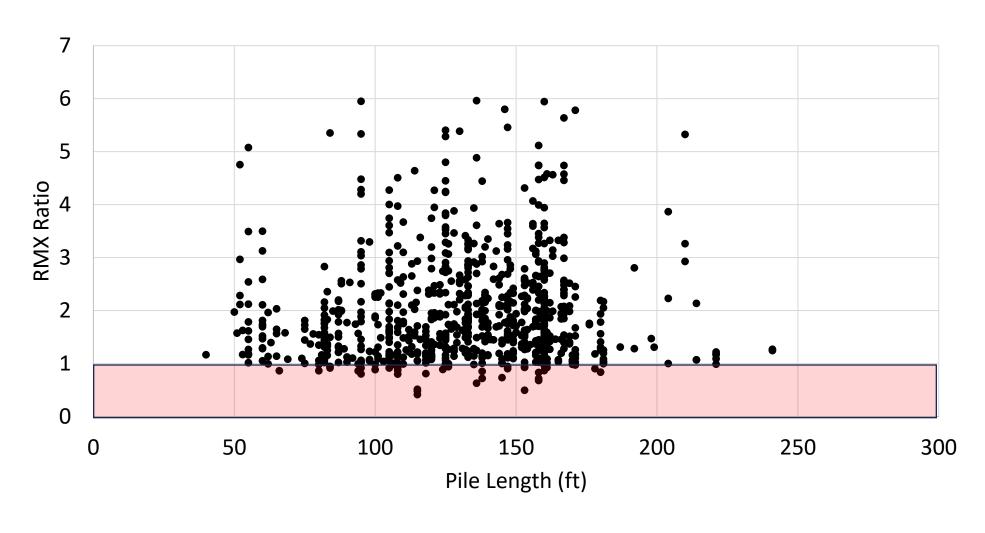

Bearing Layer (relaxation cases)

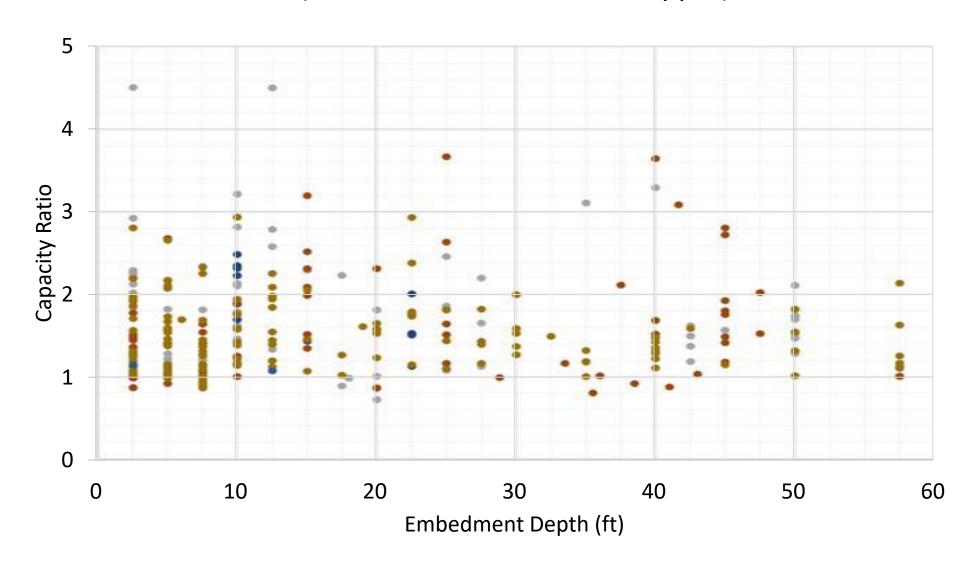

Capacity Ratio vs Pile Length

(short piles ≠ relaxation)

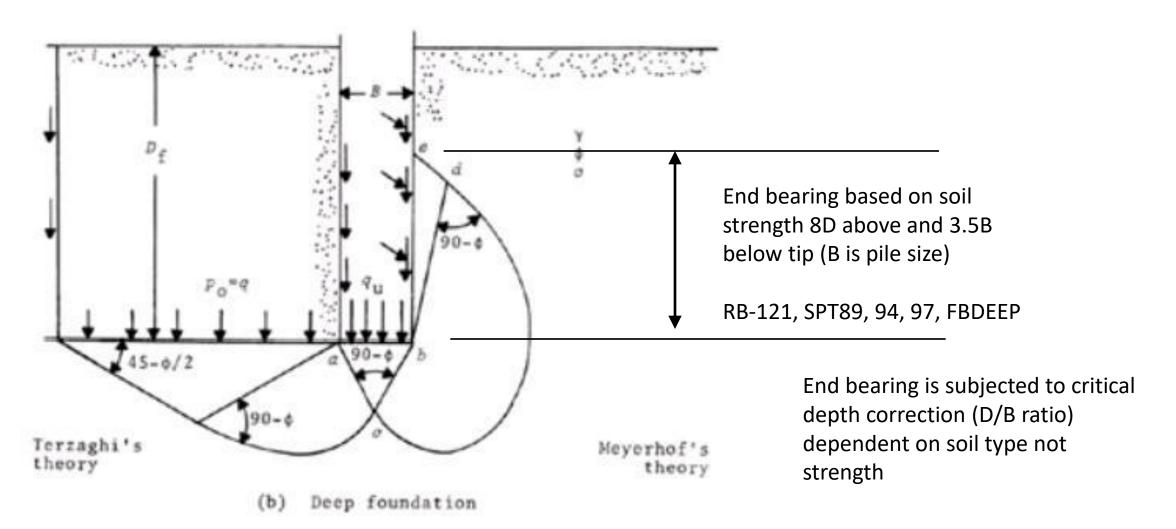

Capacity Ratio vs Embedment Depth (based on same soil type)

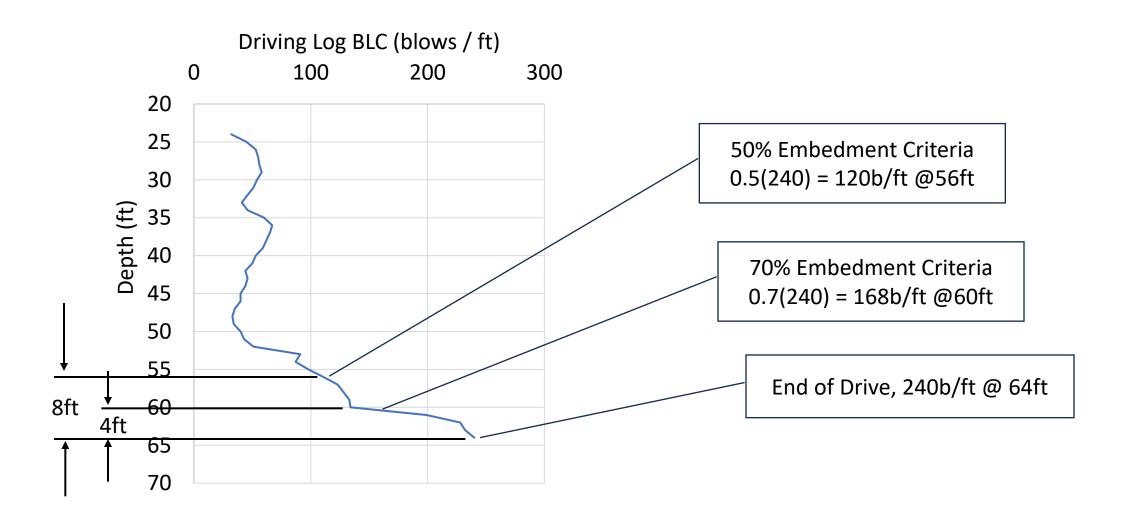

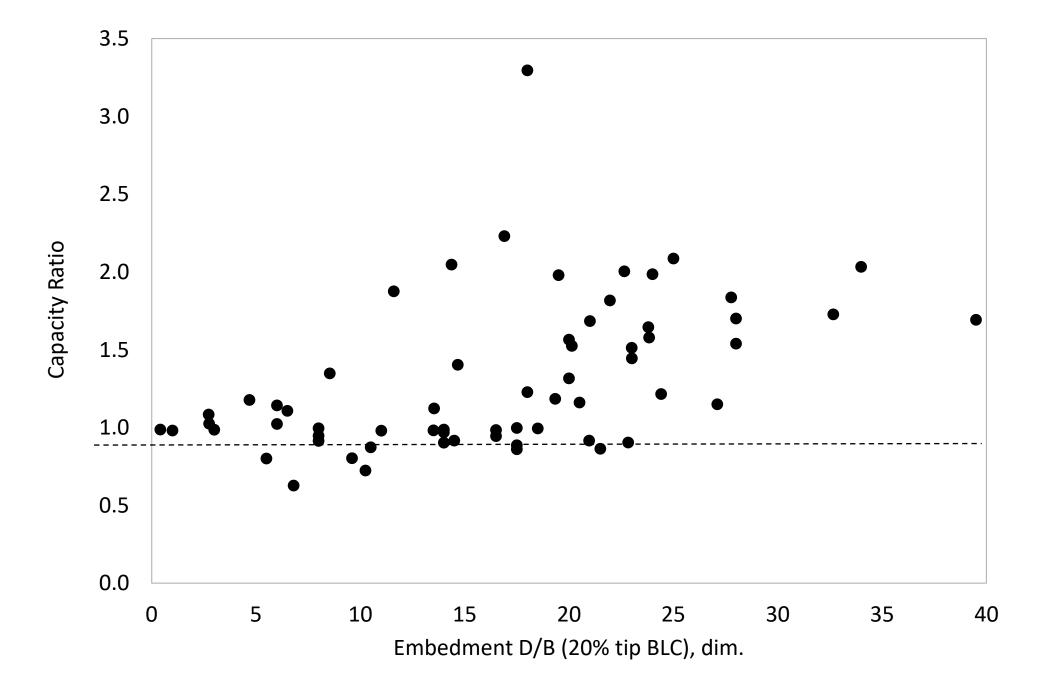

Embedment Depth

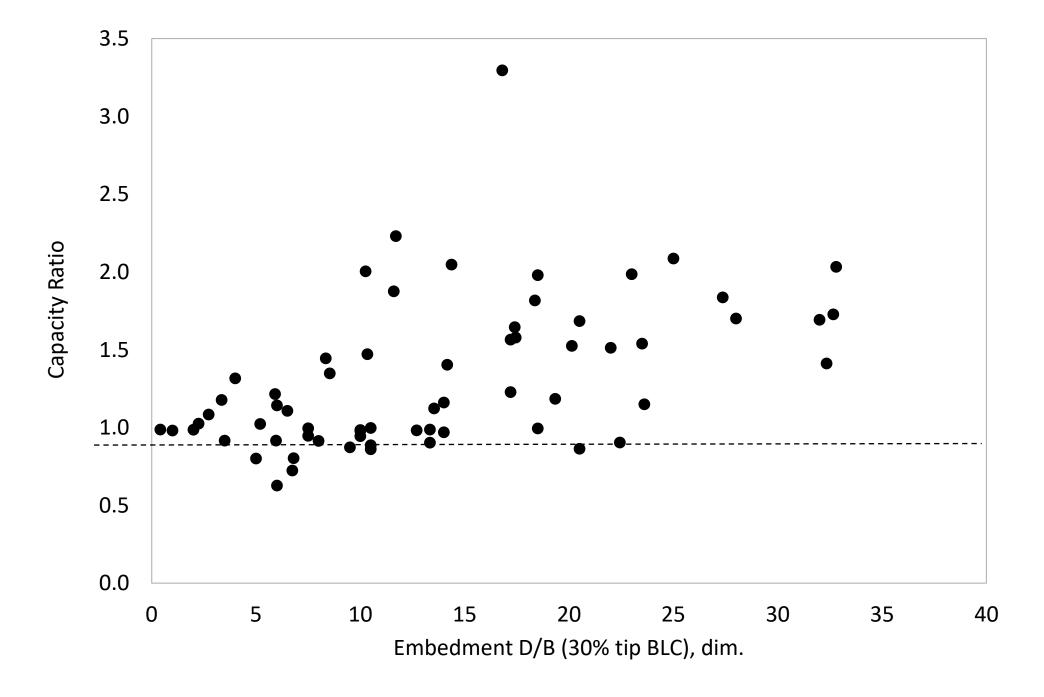

(based on soil strength?)

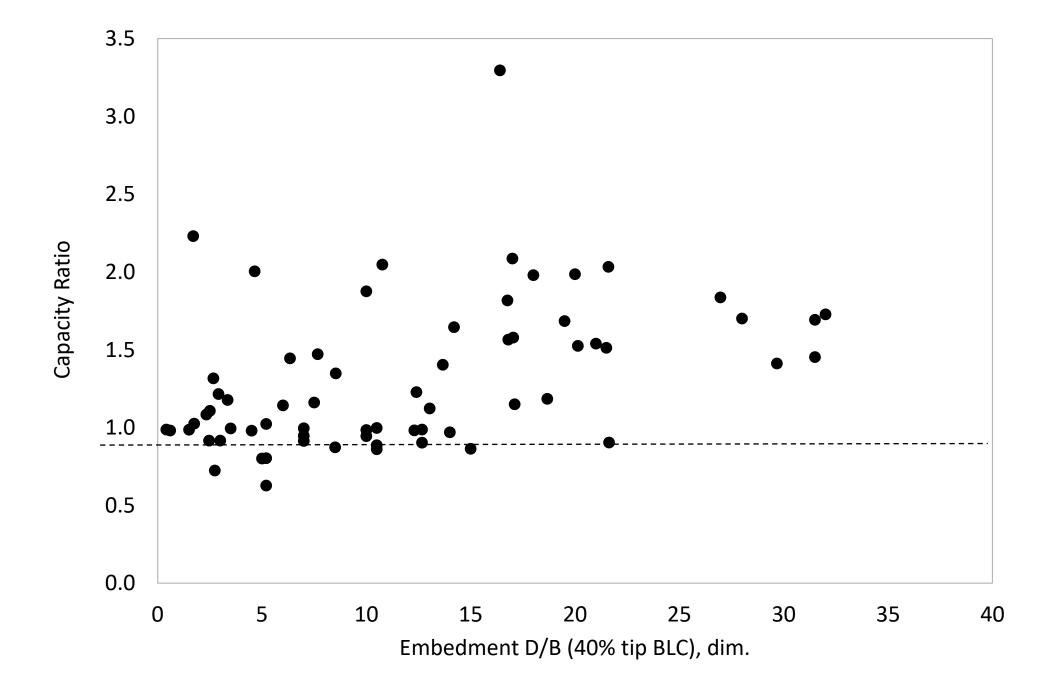

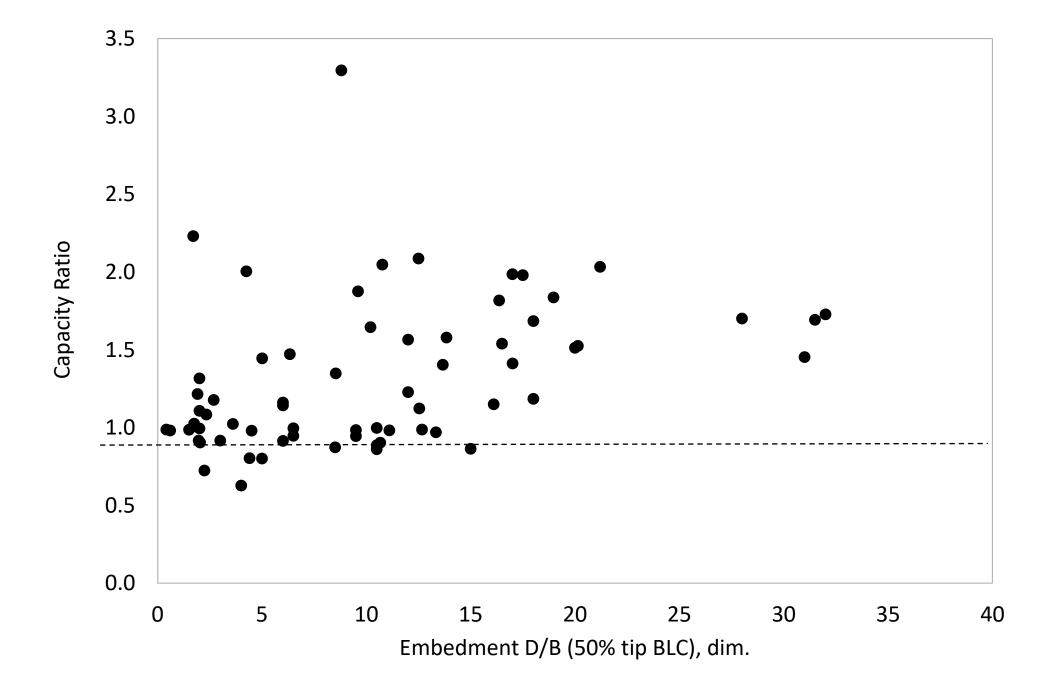

Example Strength-based Embedment Criteria

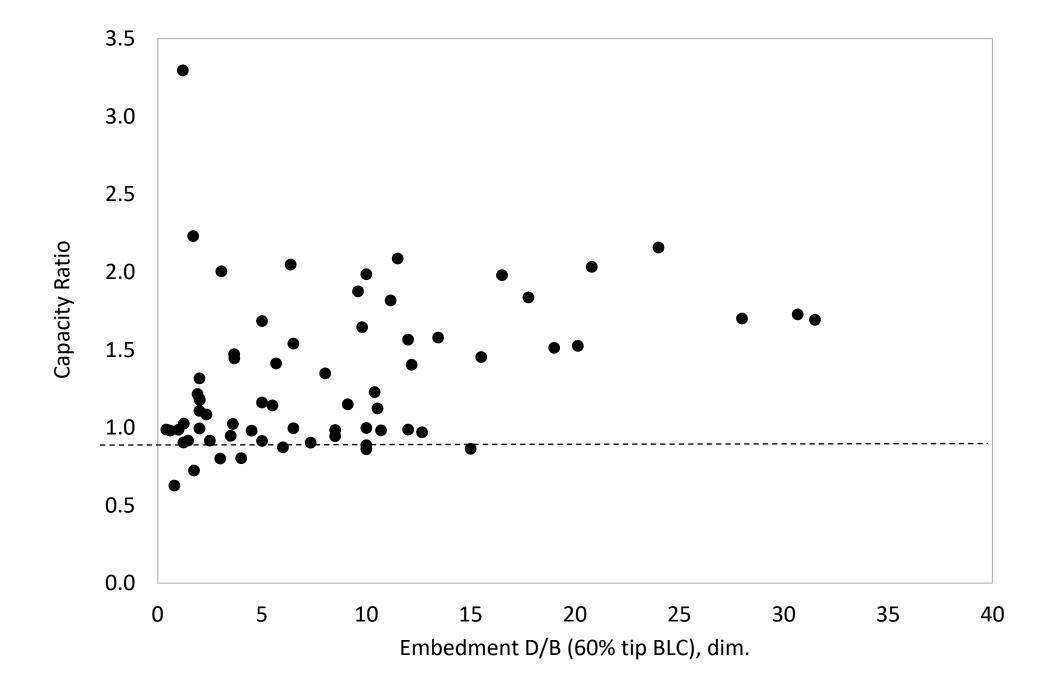

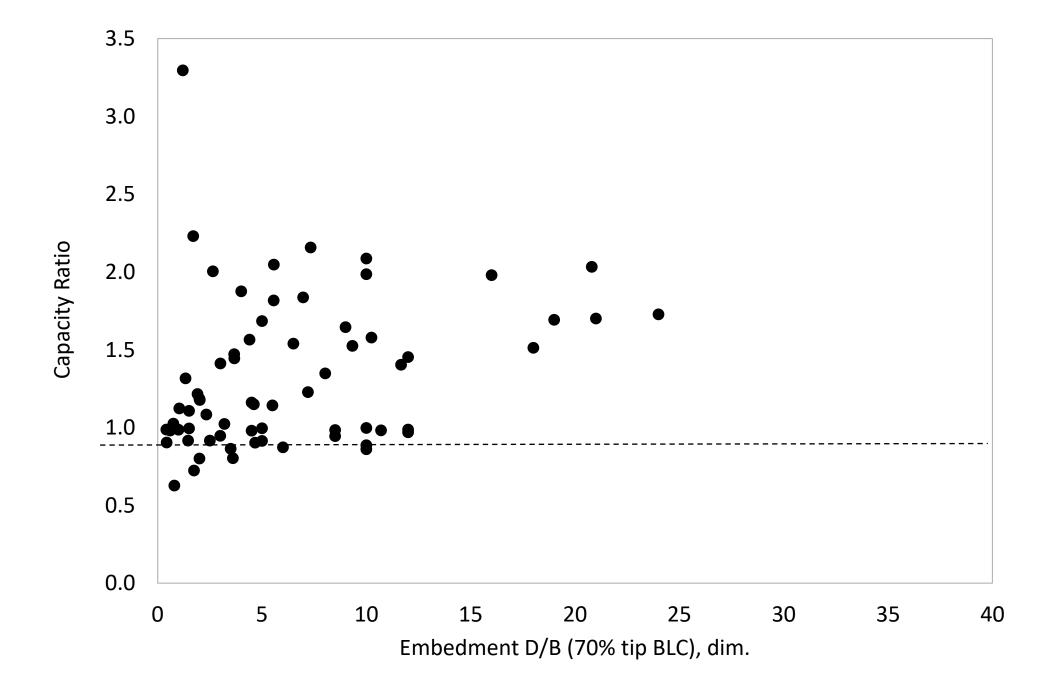

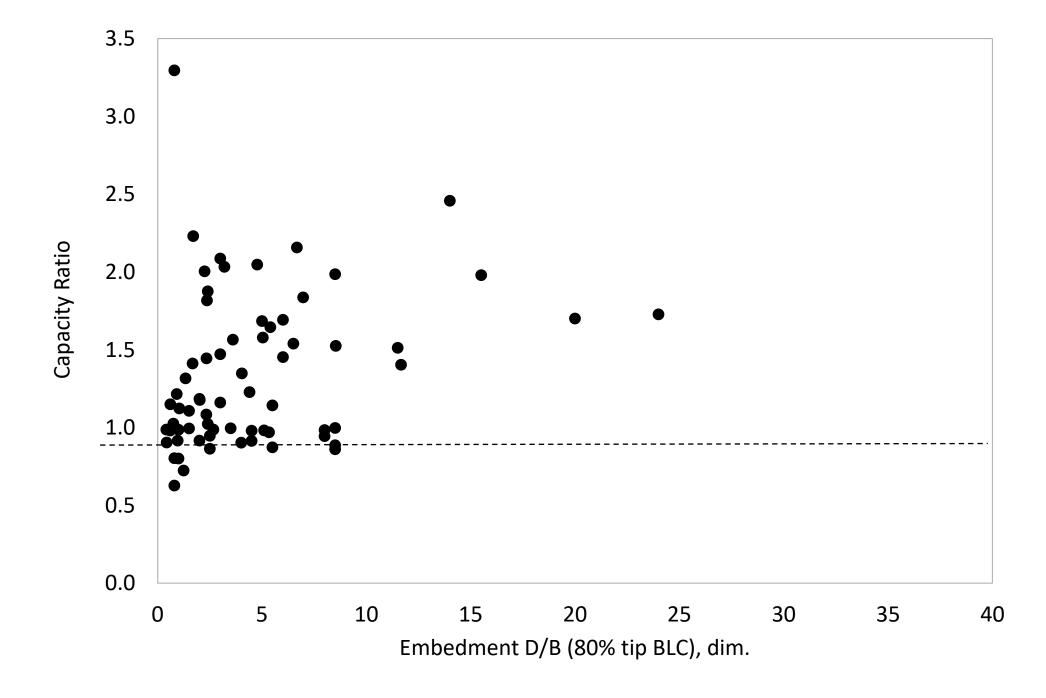

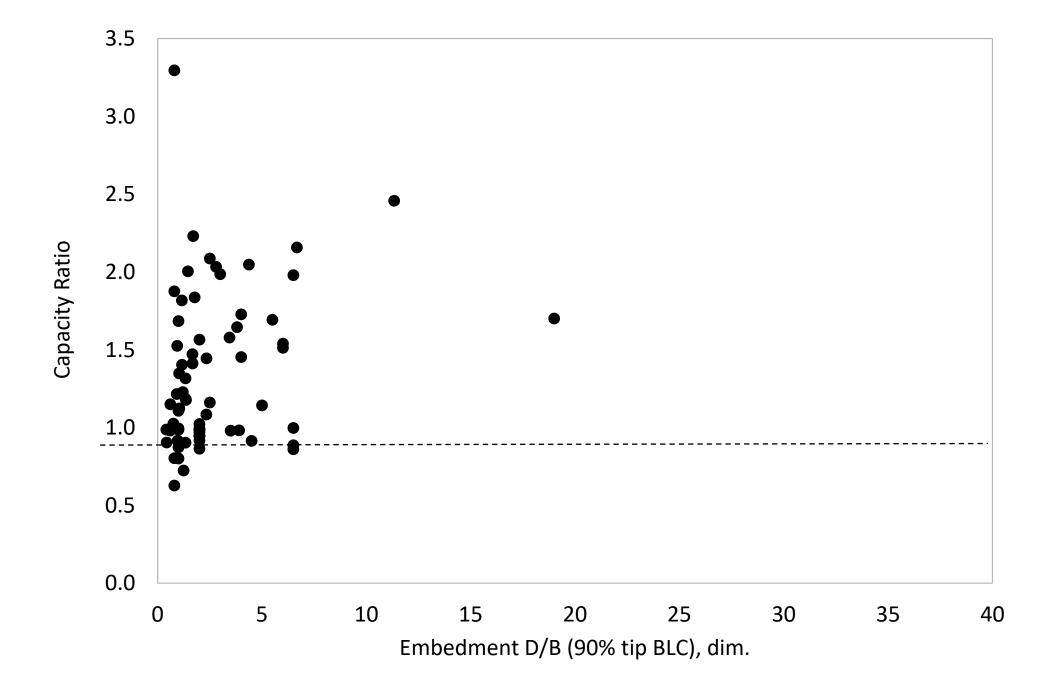

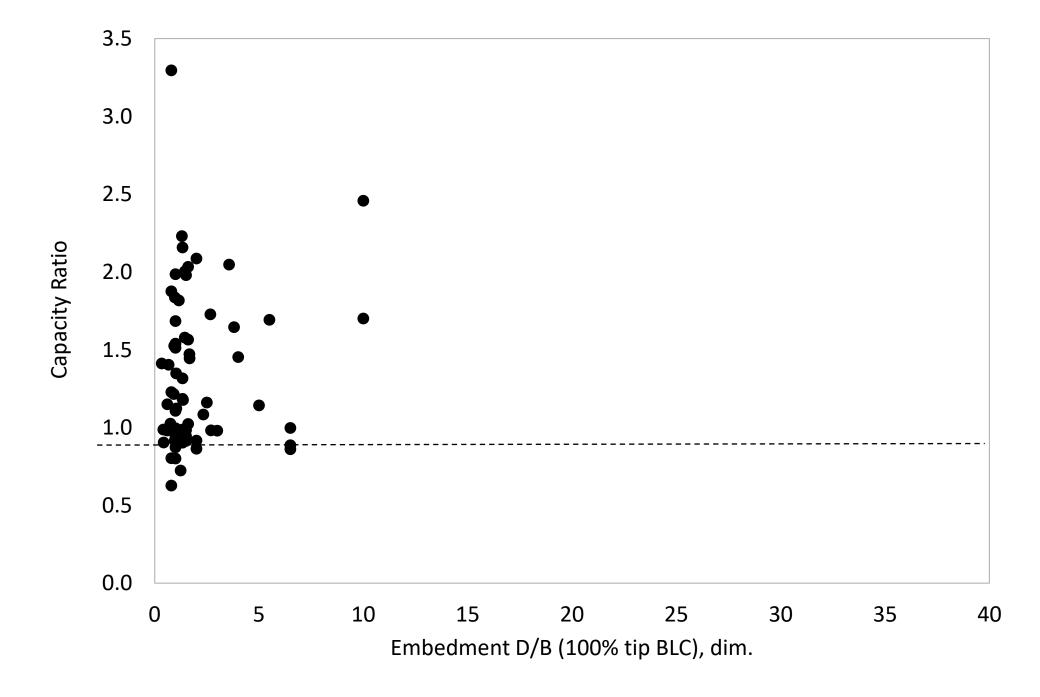

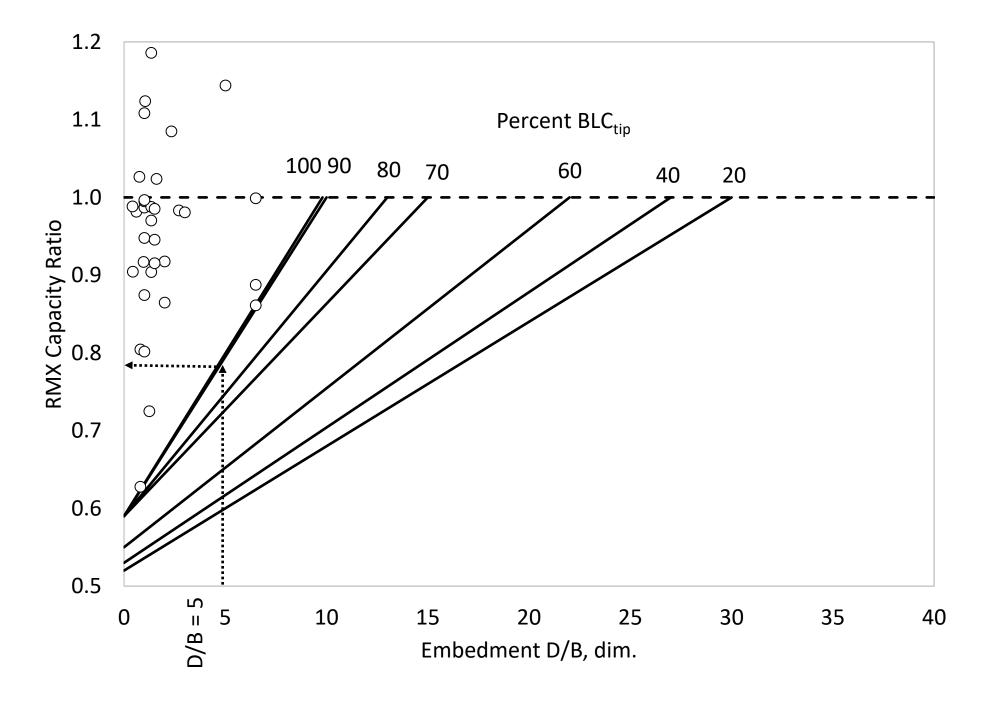

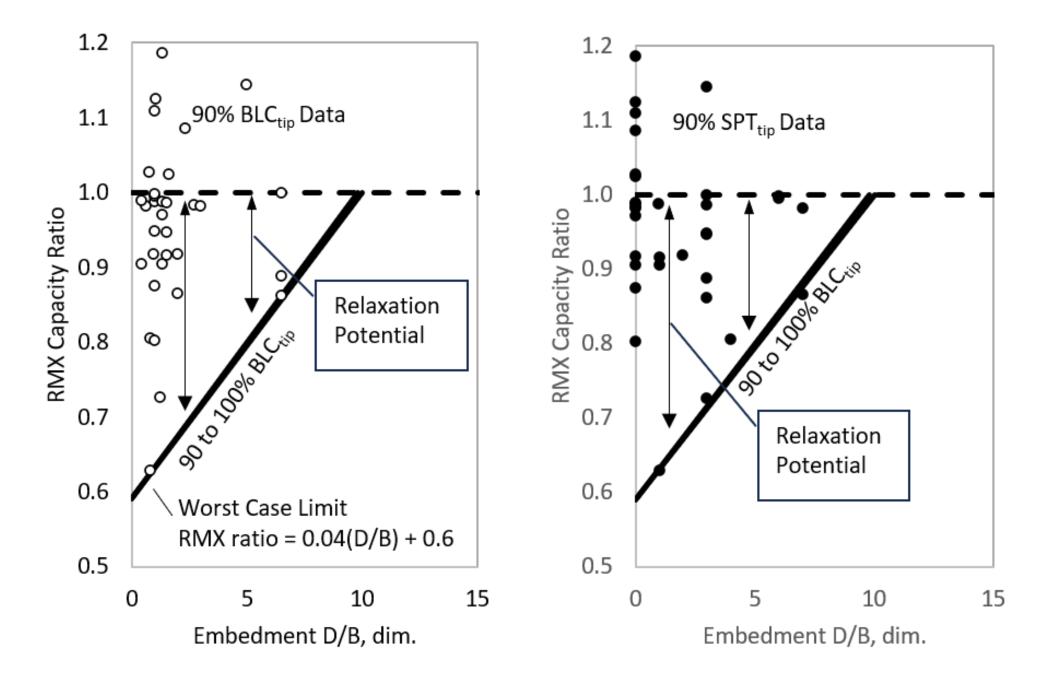

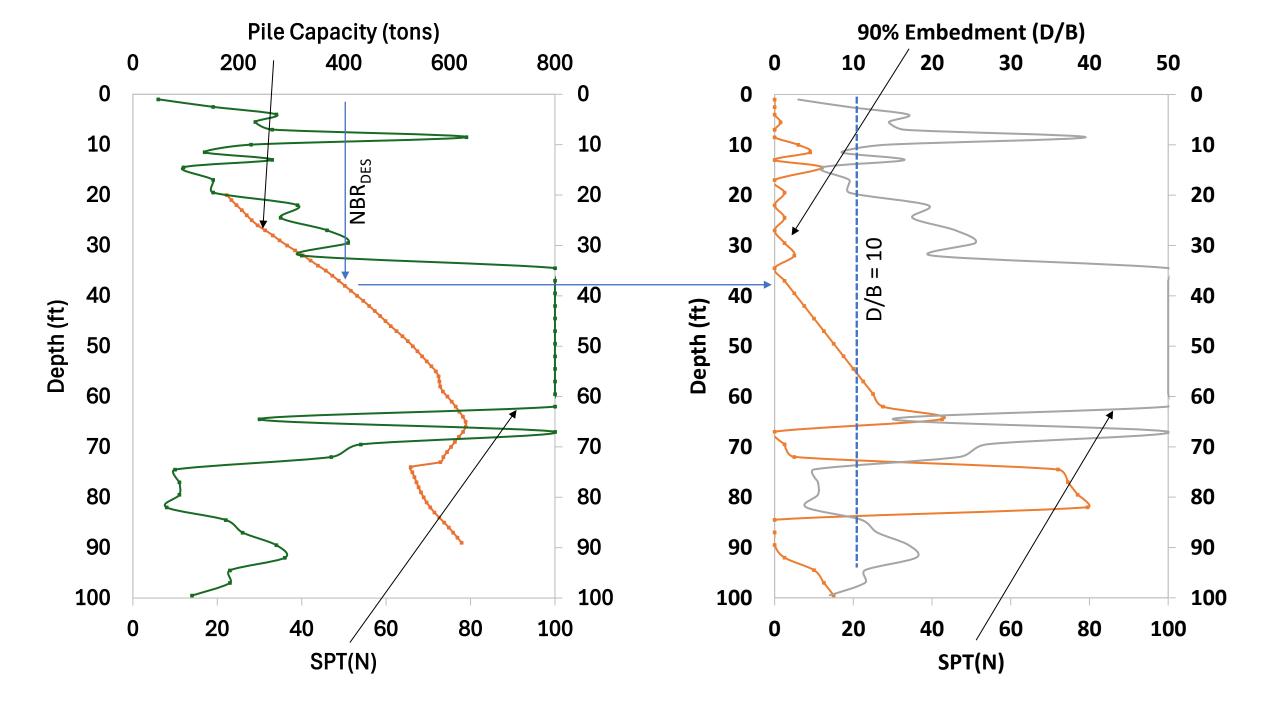

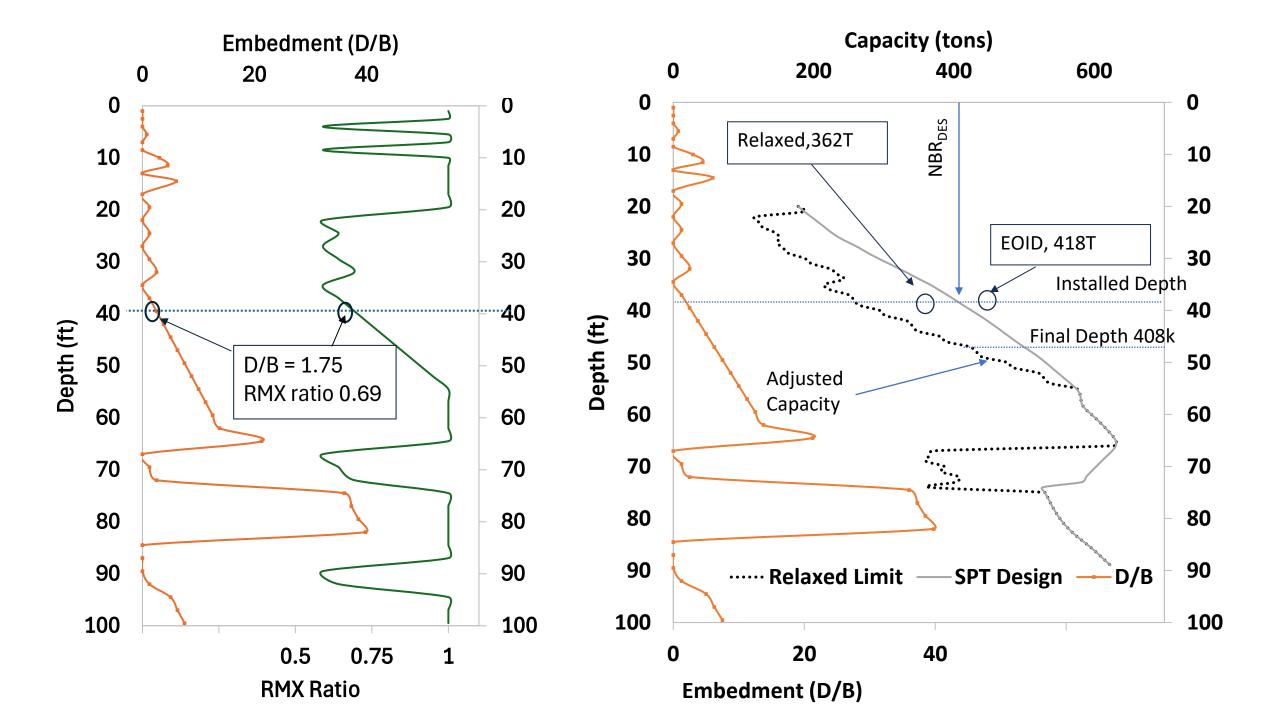

Summary

- Most relaxation cases occurred in medium dense, dense and very dense sand.
- Dilation theory is likely the best explanation
- Creep effects not found
- Pile length not specifically the cause of relaxation
- Sufficient embedment depth into competent bearing layer appears to be the strongest deterrent to relaxation
- D/B embedment > 10 showed no relaxation

Limitations

- Bearing layer correction does not address medium dense layers at higher elevations away from the pile tip which may also experience relaxation; some references suggest not as problematic
- The study examined only used end of restrike vs end of initial drive values. Relaxation that was observed during cushion changes or other intermediate installation pauses were not and could not be addressed.

Future Work (Phase II)

- A strength-based critical depth correction should be explored in lieu of the soil type method currently used; this has the potential of addressing both relaxation and critical embedment depth criteria.
- Evaluate all stops in driving (e.g. cushion changes, other) from original data set now looking at individual blows after restart of driving.

Sample Pile End of Drive Summary

```
I-100 hammer
18 inches of plywood pile cushion
2-2 inch blue nylon and 2-1 inch alum.
Ref. Elevation 13.65'
Mud Line Elevation Approximately -12 feet
