# District Five Truck Parking Study Demand Estimation 

## Truck Parking Demand Estimation

## State of the Practice

This portion of the District Five Truck Parking Study (Study) estimates future truck parking demand through forecast methodologies. The nine-county District Five Study area includes: Orange, Osceola, Seminole, Lake, Sumter, Marion, Flagler, Brevard, and Volusia. A total of five estimation approaches were reviewed; four unique methodologies for estimating truck parking demand, along with one recent study by the Florida Department of Transportation's (FDOT) District Four, were reviewed and evaluated. The following methodologies were assessed based on their approach, availability of data, and advantages and disadvantages. The methodologies that were reviewed are described below.

The first methodology considered was based on the "NCHRP Synthesis 298: Truck Trip Generation Data, A Synthesis of Highway Practice" (2001) by the Transportation Research Board (TRB). The synthesis mainly focused on the current practices for truck trip generation data. It identified the needs and uses of this data and the critical issues associated with meeting these needs. The report did not directly address truck parking demand estimates and did not provide a clear and replicable methodology for calculating these estimates. Truck parking demand was referenced only as a by-product of truck trip generation. Not enough information was provided with regard to data requirements, or the subsequent steps to estimate truck parking demand.

The second methodology that was considered was based on the "Estimating the Supply and Demand for Commercial Heavy Truck Parking on Interstate Highways: A Case Study of Interstate 81 in Virginia" study by Dr. Nicholas J. Garber, Hua Wang and Dares Charoenphol. The methodology used in this study to calculate truck parking demand estimate relied on the accuracy and quality of the data collected. The methodology defined the demand for parking as the sum of parking accumulation and the illegal parking at any given time, and the supply as the number of parking spaces available. Data collection for this methodology consisted of five steps: identifying rest areas and truck stops, inventory of rest areas and truck stops, survey of truck drivers and truck stop owners/managers, collection of traffic information, and collection of truck parking accumulation and duration data. While the study tries to take a comprehensive approach towards estimating demand, the data collection method focuses primarily on illegal parking. The study was unable to conduct regular counts and opted to assume that six vehicles would be parked illegally at any interchange that did not have a truck stop or was a freeway-tofreeway interchange, based on field observations. If this methodology were to be used, the accuracy of illegal parking counts would be very important; however, collecting accurate counts for such parking would require a substantial amount of time and cost, making it very difficult to attain.

The third methodology considered was based on "Mn/DOT: The Minnesota Interstate Truck Parking Study" by Wilbur Smith Associates and the Center for Transportation Research and Education at lowa State University. Minnesota Department of Transportation (Mn/DOT) used a model based on one recommended by AASHTO. The model estimated the demand based on overall traffic flow and on the percent of heavy commercial traffic. The model also estimated the

## District Five Truck Parking Study Demand Estimation

short-term resting need due to driver fatigue, but it did not consider additional demand due to commercial motor vehicles hours of service or staging. In 1996, Apogee Inc. developed a guidebook for a more complicated space estimation model; the model took into account factors such as availability of food, amenities, lighting, location and proximity to delivery and pick up location. This model was based on the recommendation of the $1981 \mathrm{Mn} / \mathrm{DOT}$ model for estimating truck parking spaces. The study also pointed out that data for these methods was collected through surveys, field observations and aerial photographs. The study did not provide a clear step-by-step process for calculating the demand, and it focused on current demand rather than forecasting demand.

The fourth methodology considered was based on "FHWA: Model Development for National Assessment of Commercial Vehicle Parking" report by the Federal Highway Administration (FHWA). The model formulated for this study based parking demand on a segment of the highway or corridor rather than an individual parking facility. The model predicted parking demand for the segment based on total truck-hours of travel and the time and duration of stops. The model required four main attributes: length of highway segment (km), annual average daily traffic (AADT) (vehicles per day), percent of daily traffic consisting of commercial trucks, and speed limit of highway or average truck speed (kph). All four attributes are easily accessible. The model then relied on 12 parameters: seasonal peaking factor, short-term parking duration per hour traveled (min/hour), maximum hours driven per week, average hours spent loading/unloading per week, average hours spent at home per week, average hours spent parking for rest at shipper/receiver per week, proportion of demand for rest area spaces, proportion of demand for truck stop spaces, proportion of total trucks that are short-haul, proportion of total trucks that are long-haul, peak-parking factor for short-haul trucks, and peakparking factor for long-haul trucks. The parameters for this model are based on a national survey of 2,000 commercial truck drivers that was conducted in 2002. The report encouraged the selection of parameter values that represent conditions within the local area of interest. The report outlined a detailed step-by-step process to calculate the demand through a 12-step equation.

A recent study conducted by FDOT District Four, titled "Truck Parking Supply and Demand," was also reviewed. The study focused on identifying truck parking needs in District Four. The methodology that was utilized in the study to estimate the truck parking demand was based on FHWA's report "Study of Adequacy of Commercial Truck Parking Facilities - Technical Report." The report offers a simplified version of the same methodology in "FHWA: Model Development for National Assessment of Commercial Vehicle Parking" without taking into consideration all the parameters considered in the latter study. The study also utilized calibrated factors based on another study from Pennsylvania titled: "Truck Parking in Pennsylvania." The values used from the Pennsylvania study were used as conservative estimates for the Florida region.

# District Five Truck Parking Study Demand Estimation 

## Conclusion

The FHWA method that was highlighted in the report "FHWA: Model Development for National Assessment of Commercial Vehicle Parking" was selected for this Study. This method is comprehensive as it takes into account multiple factors that affect the truck parking demand, unlike the other methods mentioned above. This method uses national commercial vehicle operator survey research and is replicable across the District Five study area. Data availability is an important factor for method selection. The segment length, annual average daily traffic, truck percentage and speed limit of the corridors that were used to calculate demand are provided as part of FDOT's Florida Traffic Information (FTI) database. The method is also clear in approach and provides a step-by-step process to calculate truck parking demand along freight corridors. Multiple planning scenarios can be developed with this method by exploring historic and future truck demand attributes (AADT, Truck Percent, and Haul Type).

## Demand Estimation Approach

The corridor model selected for this study bases the parking demand for highway segments on total truck-hours of travel and the time and duration of stops, rather than the parking characteristics of a parking facility. The model also considers the ratio of short-haul to long-haul trucks and the inclination to use public or private parking spaces for different purposes.

The key parameter in the model is the number of hours of parking required by drivers given the number of hours they travel (FHWA-RD-01-159). Therefore, the Federal Hours of Service (HOS) regulations have an indirect, but significant, effect on the model as they set the maximum number of hours truck drivers are allowed to drive; each HOS regulation has its own specific restrictions. The primary data input for the model and their sources are summarized in Table 5-1. The model produces a peak-hour estimate of parking spaces demanded for a highway segment (FHWA-RD-01-159).

Because short-haul drivers (i.e., those not making overnight trips) make relatively short stops, parking demand is based on minutes of parking time per hour on the road. For long-haul trips, when an overnight rest stop is required on the road, hours of parking demand are calculated using a ratio of parking time to driving time (FHWA-RD-01-159).

## District Five Truck Parking Study Demand Estimation

Table 5-1 | Primary Data Input Requirements

| Model |  |  |
| :---: | :---: | :---: |
| Variable | Description | Data Source |
| L | Length of highway segment (Miles) | For existing condition FTI database was used; <br> For future conditions the CFRPM 6.1 outputs were used. |
| AADT | Annual average daily traffic <br> (vehicles per day) | For existing condition FTI database was used; |
| For future conditions the CFRPM 6.1 outputs were used. |  |  |

Source: FHWA-RD-01-159
Table 5-2 provides the default parameters of the model adjusted to reflect changes in HOS regulations along with calibrating the parameters using values from the "Truck Parking in Pennsylvania" study. This adjustment was done to modify the parameters of the model to better suit the Florida region.
A seasonal peaking factor of 15 percent was used to represent all vehicles under peak periods. Short-term parking was assumed to be five minutes for each hour traveled. The assumption is based on professional judgment and the information obtained from drivers (FHWA-RD-01-159).

Table 5-2 | Demand Model Parameters

| Model Variable | Description | Default Value |
| :---: | :---: | :---: |
| $\mathrm{F}_{\mathrm{S}}$ | Seasonal peaking factor | 1.15 |
| $\mathrm{D}_{\text {ST }}$ | Short-term parking duration per hour traveled (min/hour) | 5 |
| $\mathrm{T}_{\text {DRIVING }}$ | Maximum hours driven per week | 55 |
| Tloading/unloading | Average hours spent loading/unloading per week | 15 |
| $\mathrm{T}_{\text {Home }}$ | Average hours spent at home per week | 42 |
| T ${ }_{\text {SHIPPER/RECIEVER }}$ | Average hours spent parking for rest at shipper/receiver per week | 19 |
| $\mathrm{P}_{\text {RA }}$ | Proportion of demand for rest area spaces | 0.23 |
| $\mathrm{P}_{\text {TS }}$ | Proportion of demand for truck stop spaces | 0.77 |
| $\mathrm{P}_{\text {SH }}$ | Proportion of total trucks that are short-haul | 0.36 or 0.07* |
| $\mathrm{P}_{\text {LH }}$ | Proportion of total trucks that are long-haul | 0.64 or 0.93* |
| $\mathrm{PPF}_{\text {SH }}$ | Peak-parking factor for short-haul trucks | 0.058 |
| $\mathrm{PPF}_{\text {LH }}$ | Peak-parking factor for long-haul trucks | 0.063 |

## District Five Truck Parking Study Demand Estimation

The maximum hours driven per week is set to 55 hours according to Hours of Service regulations set by the Federal Motor Carrier Safety Administration (FMCSA). The 11-Hour Driving Limit rule states that a driver may drive a maximum of 11 hours after 10 consecutive hours off duty. The 14-Hour Limit states that the driver may not drive beyond the 14th consecutive hour after coming on duty following 10 consecutive hours off duty, and that the offduty time does not extend the 14-hour period. The 60/70-Hour Limit rule states that the driver may not drive after 60/70 hours on duty in $7 / 8$ consecutive days. A driver may restart a $7 / 8$ consecutive day period after taking 34 or more consecutive hours off duty.

The maximum hours driven in an 8-day period would be: $70 * \frac{11}{14}=55 \mathrm{hr}$
Several parameters were based on a national survey of commercial truck drivers that was administered to over 2,000 drivers across the United States. The responses from the survey were used to calibrate the values relying on the needs, preferences and travel patterns of the drivers. Driver survey results were used to determine values for the following parameters; average hours spent loading/unloading per week, average hours spent at home per week, average hours spent parking for rest at shipper/receiver per week, and the portion of demand for public rest area and private truck stop spaces (FHWA-RD-01-159).

The average hours spent loading/unloading the truck (whether the driver actually loads/unloads or waits for it to be done; "driver detention") was determined from a question that asked drivers how many hours, on average, per week do they spend loading or unloading their trucks. The average response to this question was approximately 15 hours per week (FHWA-RD-01-159).

The average hours spent at home per week was determined from a question in the driver survey that asked drivers how many days, on average do they sleep at home each month. The average response to this question was 6.7 days per month, which translates into approximately 42 hours in eight days (FHWA-RD-01-159).

The average response to the "loading/unloading location" question was 2.6 times per week (FHWA-RD-01-159). Based on the District Four study, the median duration for long-term parking from the "Truck Parking in Pennsy/vania" study was 7.25 hours (FDOT D4). Using this information, 2.6 times per week translates into approximately 19 hours per week of rest at shippers/receiver.

From this, the amount of time a driver will demand parking along the highway in a week can be determined by taking the total number of hours in an eight-day period (192) and subtracting the time that drivers spend on-duty driving ( 55 hours), on-duty not driving ( 15 hours), off-duty ( 42 hours), and parking other places than along the road (19 hours). Therefore, the total hours of parking demanded per long-haul truck per week, used for this model, is 61 hours.

While Table 5-3a, Table 5-3b, and Table 5-4 show the data from the FHWA survey and illustrates how the data could be used to derive the values for the proportion of demand for rest area and truck stop spaces; it is important to note given evolving truck driver needs and locational preferences, study findings pertaining to parking space demand is reported in total values. This reporting approach focuses on total potential demand and associated needs.

## District Five Truck Parking Study Demand Estimation

The values were derived as follows:

1) The number of driver responses for each preference category (i.e., rest area, truck stop, no preference) was weighted according to the average amount of time spent parking for each activity (thereby converting number of drivers into number of truck-hours of parking according to preference);
2) The truck-hours of parking were then summed for each preference category;
3) The truck-hours of parking in the "no preference" category were then divided evenly between the rest area and truck stop preference categories; and
4) The total truck-hours of parking for rest areas and truck stops were then divided into the overall total truck-hours of parking. This process resulted in values for the proportion of parking demand for rest area and truck stop spaces of 0.23 and 0.77 , respectively (FHWA-RD-01-159).

| Total | $5,984.25$ | 1.00 |

Source: FHWA-RD-01-159
The "FHWA: Model Development for National Assessment of Commercial Vehicle Parking" defines short-haul as trips that could be completed without an overnight stay. Therefore, the maximum one-way distance for short-haul trips would typically be 200 to 250 miles, depending on speed, length of workday, and the number and length of stops. The default proportion of total trucks that are short-haul and the default proportion of total trucks that are long-haul values are based on national averages for long-haul to short-haul truck ratios. For short-haul the value used was 0.36 and for long-haul the value used was 0.64 . These values were the default values in "FHWA: Model Development for National Assessment of Commercial Vehicle Parking," and are the default values for this study. The default values for the peak-parking factors for short-haul and long-haul trucks were based on the values extracted from "Truck Parking in Pennsylvania" study.
Utilizing the average short-haul parking duration of 22 minutes, and 2.11 percent for peak-hour short-haul parking demand utilization, the short-haul peak-parking factor is:

$$
\frac{1 \text { veh }}{\left(\frac{22}{60}\right) h r s} * 0.0211=0.058
$$

Using the median long-haul parking duration of 435 minutes, and 45.35 percent for peak-hour long-haul parking demand utilization, the long-haul peak-parking factor is:

$$
\frac{1 \text { veh }}{\left(\frac{435}{60}\right) \mathrm{hrs}} * 0.4535=0.063
$$

Table 5-5 represents the terms calculated and their description. Table 5-6 shows each equation along with an example solving the demand for the following values:

$$
L=130 \text { Miles } \quad \text { AADT }=17,500 \quad P_{t}=18 \% \quad S=65 \mathrm{MPH}
$$

## District Five Truck Parking Study Demand Estimation

## District Five Truck Parking Study Demand Estimation

For this example, the total peak-hour parking demand for public rest areas is $3+80=83$ trucks, and the total peak-hour parking demand for private truck stops is $10+268=278$ trucks.
Figure 5-1 shows an example of the truck parking estimation spreadsheet derived in Microsoft Excel.

Figure 5-1 | Truck Parking Estimation Spreadsheet (Screenshot)

## Sensitivity Testing and Probabilistic Parameters

In order to eliminate outliers in the results, the methodology was subjected to a sensitivity test. Two parameters and one input were varied to represent minimum, mean and maximum scenarios. This step provides for probabilistic model outputs which account for uncertainty and fluctuation in parking demand; and recognizing that not all truck spaces are needed at the same time. The varied input was the truck percentage that allowed for the variation in the amount of trucks on the roadways being studied. These truck percentages were obtained from the FTI database for existing data and the Central Florida Regional Planning Model (CFRPM) 6.1 outputs for future data. The two other factors that were varied were the proportion of total trucks that are short-haul/long-haul percentages and the peak-parking factors.

For the long-haul and short-haul percentages, it was assumed to be five percent for long-haul and 95 percent for short-haul for the minimum scenario and vice-versa for the maximum scenario. As for the peak-parking factors, the values were calibrated using the median duration for long-haul parking and the mean for the short-haul parking utilized in both the FDOT "Truck Parking Supply and Demand" that was developed for District Four, and the "Truck Parking in Pennsylvania" study. This is assuming peak-parking demand at 0 percent and 20 percent for short-haul and long-haul, respectively, for the minimum scenario and five percent to 60 percent, respectively, for the maximum scenario. Using these values, the peak-parking factors yielded were zero for short-haul and 0.028 for long-haul in the minimum scenario and 0.136 and 0.083 ,

## District Five Truck Parking Study Demand Estimation

respectively, for the maximum scenario. As for all the mean scenarios, the default values that were noted in Table 5-2 were used. Table 5-7 summarizes the values used for each scenario.

Table 5-7 | Values Used for Each Scenario

| Variable | Min | Mean | Max |
| :---: | :---: | :---: | :---: |
| $P_{\text {SH }}$ | $95 \%$ | $36 \%$ | $5 \%$ |
| $P_{\text {LH }}$ | $5 \%$ | $64 \%$ | $95 \%$ |
| PPF $_{\text {SH }}$ | 0 | 0.058 | 0.136 |
| PPF $_{\text {LH }}$ | 0.028 | 0.063 | 0.083 |

To provide probabilistic outputs and represent the variation in parking demands, the sensitivity analysis used 27 scenarios, a combination of the factors listed in Table 5-8, for each roadway segment to report a range (minimum, mean, and maximum) of truck parking space needs. The results were then arranged from lowest to highest, and five of the highest and lowest values were discarded. This process also removes any extremes on both ends that were created by the factorial nature of the analysis. Table 5-8 shows the composition of each scenario.

Table 5-8 | Scenario Composition

| Result Number | Truck volume | Short Haul to Long Haul | Peak Parking Factor |
| :---: | :---: | :---: | :---: |
| 1 | Min | Min | Min |
| 2 | Min | Min | Mean |
| 3 | Min | Min | Max |
| 4 | Min | Mean | Min |
| 5 | Min | Mean | Mean |
| 6 | Min | Mean | Max |
| 7 | Min | Max | Min |

| 26 | Max | Max | Mean |
| 27 | $M a x$ | $M a x$ | $M a x$ |

FDOT's "Truck Parking Supply and Demand," conducted by District Four, also included a similar sensitivity analysis process. In the District Four study, 45 scenarios for each segment were calculated by varying the truck volume, truck ratio and peak-hour demand. Following preliminary calculations, the five highest and lowest results were discarded.

## Corridors Identified for Truck Parking Demand Estimation

Trucks serve as the primary freight mode in Central Florida and this is true for most major metropolitan areas as generally trucks are the most flexible and responsive of all the freight modes. The highway network and supportive infrastructure are important elements of Central Florida's freight transportation system; providing access and connectivity for both long- and short-haul shipments.

Major freight corridors within District Five were identified and utilized in the analysis for this Study. For the demand estimation approach, two state and federally designated roadway networks were identified for the demand estimation calculation based on their interregional connectivity and freight carrying significance. The networks identified are Florida's Strategic Intermodal System (SIS) Corridors and connectors and segments of the National Highway Freight Network (NHFN) within District Five. Based on FDOT estimates, the current designated SIS system carries 55 percent of total traffic and more than 70 percent of all truck traffic on the State Highway System. To ensure full regional network coverage, additional roadway segments were included to provide comprehensive east-west and north-south connectivity.

These major corridors and their total segment length are summarized in Table 5-9. In order to conduct demand estimation, a few key inputs needed to be obtained. The roadway corridors were divided and organized by county in order to obtain refined results which illustrate supply and demand geographically.

For existing conditions, 2016 information from the FTI database was obtained while CFRPM 6.1 outputs (AADT and Truck Percentage) were used for 2025 and 2040 future year forecasting and analysis. A GIS analysis was conducted to extract and calculate the following demand estimation formula inputs for each study corridor segment:

- Length (miles);
- Posted Speed Limits (mph);
- Annual Average Daily Traffic; and
- Truck Percentage.

## District Five Truck Parking Study Demand Estimation

Figure 5-2 shows the corridors utilized for the Truck Parking Demand Estimation, their end points, and their segment IDs that correspond with Table 5-9. Table 5-10 shows the segment limits and counties in which the corridors reside. Table 5-11 reports the segment length and average posted speed limit. Table 5-12 through Table 5-14 show the average AADT counts and the minimum, mean, and maximum truck percentages used to vary the truck volumes in the model for each of the following years: 2016, 2025, and 2040.

## District Five Truck Parking Study Demand Estimation

## Demand Estimation Findings

Truck parking demand estimation findings are summarized in Table 5-15 through Table 5-19, moving from the segment level, to the corridor level, to the county level with totals for District Five. The arrangement of the tables allows for each segment to be viewed individually followed by how each segment contributes to each roadway corridor, and ultimately how they contribute to each county's parking space demand.

In summary, the full range of truck parking space demand for 2016 is 843 to 6,648 spaces, while in 2025 the minimum increases from 1,133 to 4,118 spaces; and in 2040, 1,360 to 10,005 truck parking spaces are estimated. Table $\mathbf{5 - 1 5}$ shows the Segment results for each year, providing a minimum, mean, and max demand levels.

## District Five Truck Parking Study Demand Estimation

## County-Level Summary

Based on the county-level segmentation of the estimation corridors described in Table 5-11, corridors-level findings were organized geographically to estimate county-level truck parking space demand. Table 5-17 through Table 5-19 shows the County results for each horizon year, providing a minimum, median, mean, and maximum demand levels. It is suggested and has been the practice of other studies utilizing this approach, given the factorial nature of the methodology, to focus not on the full range of forecasted demand (minimum to maximum) generated by the model but rather a scenario of demand within the range of median and mean values. The reporting approach provides a probabilistic range of truck parking space demand while acknowledging the limitations and uncertainties of the estimation methodology.

Table 5-17 | County Demand Results, Existing Conditions, 2016

| County | Min | Median | Mean | Max |
| :---: | :---: | :---: | :---: | :---: |

| Volusia | 118 | 378 | 416 | 886 |
| Total | 1,360 | 4,294 | 4,943 | 10,005 |

## It is important to note:

While the approach to calculating the parking demand is comprehensive, it still has limitations and assumed uncertainty, especially in calculating long-range (future) demand. The parking demand in this model is based on truck volume, speed limit, and segment length; and does not take into consideration other factors such as changes in regulatory policies (HOS rules, local ordinances, etc.) and technological advancements in transportation logistics such as autonomous and connected vehicles, or even other modes for transporting goods and services. It is acknowledged that these factors will affect future truck parking demand.

This data and analysis was developed for use by FDOT for planning purposes. FDOT is not liable for any direct, indirect, special, incidental or consequential damages (such as, but not limited to damages for loss of profits, business, savings or data) related to the use of this product or data, or its interpretation. This information is publicly available, and is provided with no warranty or promises of any kind whatsoever, expressed or implied, including warranties for merchantability or fitness for a particular purpose. While every effort is made to confirm the accuracy of the data and any analytical methods used to develop the data, no assurance of accuracy can be or is given. By using this data in any way, the User is acknowledging this limitation, and is agreeing to use the data at his or her own risk.

[^0]:    *Values depend on proximity of analysis segment to a metropolitan area:0.36/0.64 for segments within 320 kilometers (200 miles) of a city of 200,000 people or more, 0.07/0.93 otherwise.
