*SI is the symbol for the International System of Units. Appropriate rounding should be made to comply with Section 4 of ASTM E380.*
Transportation agencies are increasingly interested in measuring and forecasting system performance and the impact of advanced technologies and strategies on existing and future year conditions. The goal of this project is to support these measurements and forecasting by taking advantage of state-of-art models, methods, and parameters and available of data from multiple sources. The potential of using a tool as a basis for this support is explored. The specific objectives of this project are:

- identifying a set of performance measures that can be used as a basis for assessing system performance and comparing improvement alternatives;
- identifying methods to predict performance measures for use in performance and impact assessment;
- identifying business processes that can benefit from the utilization of the project development; and
- enhancing and extending models in an existing tool to allow the assessment of system performance and the impacts of additional advanced and emerging technologies.
EXECUTIVE SUMMARY

E1. BACKGROUND

Agencies are increasingly interested in measuring system performance and the impact of advanced technologies and strategies on existing and future year conditions. This interest increased with the MAP-21 and later the Fast-Act federal legislation emphasis on establishing performance goals focusing on seven areas: safety, infrastructure conditions, congestion reduction, system reliability, freight, environmental sustainability, and project delivery time. The federal legislations require states and metropolitan planning organizations (MPOs)/transportation planning organizations (TPO)/Transportation Planning agency (TPA) to identify performance measures and associated targets and including these targets in the state and MPO plans. For existing conditions, this estimation can be done based on data collected from multiple sources such as statistics office detectors, traffic management system detectors, incident and crash databases, weather agencies, and other sources of data. For future conditions, there is a need to identify models and methods that can be used to support the estimation of system performance. These models will have to be supported by data from multiple sources to ensure their accuracy in estimating future conditions. In 2008, the Florida Intelligent Transportation System (ITS) Evaluation (FITSEVAL) tool was developed for the Florida Department of Transportation (FDOT) to estimate the impacts of advanced strategies on system performance. This tool has the potential to be used to forecast system performance with and without technology and strategy deployment and thus support transportation agency investment decisions.

E2. GOALS AND OBJECTIVES

The goal of this project is to support agencies in measuring and forecasting system performance and the impact of advanced technologies and strategies on existing and future year conditions by taking advantage of state-of-art models, methods, and parameters and available of data from multiple sources. The potential of using a tool as a basis for this support is explored. The outcome of this project will allow a better selection of alternatives for implementation based on combinations of forecasted performance measures that are related to the state and regional goals and objectives. The specific objectives of this project are:

- identifying a set of performance measures that can be used as a basis for assessing system performance and comparing improvement alternatives;
- identifying methods to predict performance measures for use in performance and impact assessment;
- identifying FDOT and MPO business processes that can benefit from the utilization of the project development; and
- enhancing and extending existing models in FITSEVAL to allow the assessment of system performance and the impacts of additional advanced and emerging technologies.

E3. POTENTIAL TOOL SUPPORT OF BUSINESS PROCESSES

Table E-1 summarizes the FDOT and MPO/TPO/TPA business processes and the corresponding potential support that can be provided by FITSEVAL. It should be noted that only a subset of
these potential application will be implemented in the first version of the updated tool produced as part of this project. Additional applications can be implemented in future versions as needed.

As required by MAP-21 and FAST Act, planning is moving towards a performance-based process. In each transportation plan, performance measures are specified for each goal and objective. These performance measures are related to the safety, mobility, environment, economy, preservation, to collaboration and agency management objectives. The current version of FITSEVAL focuses on mobility, safety, and reliability. FITSEVAL can be upgraded as needed in to estimate performance measures related to other measures and show how these measures satisfy the federal and state requirements.

**E4. EXISTING PERFORMANCE FORECASTING AND ASSOCIATED TOOLS**

Based review presented in this document, it can be concluded that there are a large number of metrics that have been identified and utilized at the national level, by FDOT departments, and by various MPO/TPO/TPA in Florida. Some of these measures will be calculated in the initial version of the updated FITSEVAL. Others, will be calculated in future versions as needed. Specifically, the following can be concluded:
A wide range of performance measures have been selected, calculated, and reported by different FDOT departments for different purposes. These measures will be considered to be calculated by the developed tool. Examples of the measures are those identified in the FDOT Florida Transportation Plan (FTP), FDOT TSM&O Strategic Plan, and FDOT Multimodal Mobility Performance Measure Source Book.

Metropolitan planning organization/transportation planning organization/transportation planning agency (MPO/TPO/TPA) in Florida have included performance management into their planning process. The performance measures used by MPOs/TPOs/TPAs vary with their specific goals and objectives. The safety performance measures are more consistent among MPO/TPO/PTAs, while there is a large variation in other performance measures. There is no standard regarding what performance measures should be reported. A number of MPOs/TPOs/TPAs have set up targets according to the required national performance measures.

The final rule of the Moving Ahead for Progress in the 21st Century Act (MAP-21) have clearly specified the national performance measures in seven focus areas that need to be calculated by state and MPOs. The calculation method, data source, and reporting date for those performance measures are also provided in detail.

As MPOs/TPOs/TPAs place more emphasis on multimodal transportation system, it is recommended not only to calculate automobile-related performance measures, but also multimodal performance measures that are related to transit, trucks, pedestrians, and bicycles. The developed tool should be updated to allow the calculation of multimodal performance measures based on modeling, where possible.

A number of methods have been identified to calculate safety, mobility, reliability, and emission performance measures. These methods can be either data-based or model-based.

E.5 ESTIMATION OF PERFORMANCE MEASURES FOR BASE CONDITION

Different methods are reviewed in this study for potential use in FITSEVAL to estimate the mobility, reliability, and safety performance for the base conditions before implementing advanced technologies. The estimation can be based on real-world data, utilizing different analytical models or simulation. Methods to estimate travel time and travel time reliability are assessed in this study by comparing the resulting estimates from applying these methods to those estimated based on real-world data. Two corridors are used as case studies for assessing the accuracy of the estimates for freeways and urban arterial streets, respectively, as follows:

- I-95 northbound between NW 32nd Street and NW 103rd Street in Miami-Dade County, FL (used as a freeway case study)
- Sunrise Blvd. between US 441 and US 1 in Broward County, FL (used as an urban street case study)
Mobility Forecasting

The accuracy of the following functions to forecast speed/travel time were assessed based on comparison with data-based estimates of travel time:

- Bureau of Public Road (BPR) Curve with the parameters extracted from the Southeast Florida Regional Planning Model (SERPM) model.
- Akcelik Equation with the parameters extracted from the Express Lanes Time-of-Day (ELToD) software developed for managed lane toll assessment.
- BPR Curve with the parameters calibrated in a study conducted by Florida State University (FSU).
- Akcelik Equation with the parameters calibrated in a study conducted by FSU.
- Modified Davidson Equation with the parameters calibrated in a study conducted by FSU.
- Conical Equation with the parameters calibrated in a study conducted by FSU.
- Freeway and urban street Highway Capacity Manual (HCM) procedures.

Based on the results presented in this study, the functions that produced the best results for all three periods are the FSU-calibrated Modified Davidson model, the Akcelik function used in ELTOD, and the HCM-based freeway facility procedure. The SERPM BPR relationship worked well for congested conditions but was somewhat less accurate than other methods for uncongested conditions. The other tested models were less accurate. In general, the estimation is much more accurate for less congested conditions for all tested methods.

The functions were also tested to estimate travel times during an incident conditions. The lowest error again was observed when using the ELTOD Akcelik model and the FSU-Calibrated Davidson model. The HCM procedure predicted higher travel time compared to the real-world measures. This model, however, performs well for the PM congested conditions, which raises questions on why this high delay is estimated during incident conditions. Further examination indicates that the traffic in the HCM-based procedure takes longer time to recover from congestion caused by the incident. This could be due to not considering diverted traffic in the analysis. It should be noted that all models, except the Queueing Analysis and HCM-based procedure show that the delay occurs during the incident lane blockage duration and do not include the additional delay during queue dissipation (recovery) after incident lane-blockage clearance.

The findings suggest that the travel time forecasting methods are able to forecast travel time more accurately for freeways compared to arterial street facilities and for less congested periods. For the arterial street segment, the FSU-calibrated Modified Davidson model produced the most accurate results for the AM and PM peak periods. However, the BPR function in the SERPM model works better for the Mid-Day period. Overall, it appears that, for the arterial segment, the FSU-calibrated Davidson model performed the best, followed by the FSU calibrated BPR curve, and ELTOD Akcelik equation. Utilizing lower capacity in the equations using a previously identified function (662 veh/hr/lane vs. the 900 veh/hr/lane in the SERPM model) produced much better results.
The HCM procedures have the advantage of considering the temporal and spatial impacts of congestion since they consider the spillbacks between the roadway segments including ramps and the extended queue from one period to the next. However, these procedures require more time to prepare and fine-tune the model and the use of a software like FREEVAL, STREETVAL, or Highway Capacity Software (HCS).

Mobility measurements as required by national, state, and MPO/TPO/TPA guidance and procedures can be forecasted based on travel time estimates calculated using the functions listed above.

**Reliability Forecasting**

The travel time reliability measures reflect day-to-day variation in congestion levels due to contributing factors such as demand and capacity stochasticity, incidents, adverse weather, and work zones. Reliability can be estimated based on models that range from simple equations to HCM-based procedures to simulation-based procedures.

In this study, forecasted reliability measures was compared with reliability estimated for both the freeway case study (I-95 in Miami-Dade County) and the arterial segment (Sunrise Blvd. in Broward County) based on real-world data. The followings are the tested reliability forecasting methods in this project, all of which were developed as part of the Reliability Program of the Strategic Highway Research Program 2 (SHRP2):

- SHRP2 L03 Project Data-Poor Procedure
- SHRP2 L03 Project Data-Rich Procedure
- SHRP2 L07 Project Procedure with Default Parameters
- SHRP2 L07 Project Procedure Calibrated for Miami by Florida International University as part of the SHRP2 L38 project
- SHRP2 C11 Project Procedure
- SHRP2 C11 Project Procedure Calibrated for the Tampa Bay Region as part of a federal grant
- SHRP 2 L08 procedures as adopted in the HCM and implemented in FREEVAL and HCS.

When considering the three peaks, the models that produced the best forecasts of reliability compared to data-based reliability estimation for the freeway segment is the SHRP2 C11 model calibrated for the Tampa Bay Area and the SHRP2 L03 Data Poor Model. The model that produced the best forecasts of reliability compared to data-based reliability estimation for the urban arterial study segment is the L07 original model followed by the SHRP2 L03 data poor and L03 data rich model.
Safety Forecasting

This project identified two methods for predicting the safety performance - the Lookup Table method and the Florida Calibrated Safety Performance Functions (SPF). The Table Lookup method is based on the method used in the original version of FITSEVAL and presents the crash rate as a function of the volume to capacity ratio. The second method utilizes the calibrated SPF developed for Florida based on roadway inventory data and crash data. The updated version of FITSEVAL allows the user to estimate the safety for the base conditions using one of these two methods or estimate the base condition crashes based on real-world crash data.

E.6 EVALUATION OF ADVANCED APPLICATIONS

ITS evaluation tools require three types of parameters: 1) Outcome Performance Modification Parameters, 2) cost parameters, and 3) benefit dollar values. A discussion of these items as related to the updated FITSEVAL tool is listed below.

- **Outcome Performance Modification Parameters:** These parameters were identified in this study based on a review of multiple resources. For CV-based applications on arterials streets, the identified impact parameters were also in part based on a review of CV-based application that was conducted by the research team, as part of another research project sponsored by the FDOT research center.

- **Cost Parameters:** Cost estimation is another required component to benefit-cost analysis. The cost estimation must consider the number and types of equipment required for each type of evaluated ITS deployment. FITSEVAL includes initial cost, operation and maintenance cost, estimated interest rate, and equipment life-time. The study team reviewed various cost data sources and identified cost estimates. It should be pointed out that there is a lot of uncertainty in the cost of emerging technologies like those associated with CV and automated vehicle (AV)-based applications. Thus, the provided values should be considered as a starting point and further information should be used if more accurate costs can be estimated.

- **Conversion to Dollar Values:** An important component of benefit-cost analysis is to convert ITS impacts to dollar values. The original version of FITSEVAL has default parameters to convert the values of the estimated outcome performance measures to dollar values. An effort by the Florida Department of Transportation (FDOT) District 5 recommended updates to these parameters. The transportation Benefit-Cost Analysis wiki (B-C Wiki) that is sponsored by the TRB Committee on Transportation Economics ([http://bca.transportationeconomics.org/](http://bca.transportationeconomics.org/)) presents a detailed set of recommended values. These and other sources were reviewed and updated values were selected for use in the new version of FITSEVAL.

- **Uncertainty Consideration:** Benefit–cost analyses of ITS alternatives produce point estimates of the return on investment of ITS deployments. These analyses used default or user input values of the cost, benefit, and dollar values of the benefits. However, there is a great amount of uncertainty associated with these parameters. The values of the parameters as reported in previous evaluation studies vary widely. Decision makers may not be willing to accept an alternative that has an acceptable average or median benefit–cost ratio but has a 25% probability of having a low benefit–cost ratio or if there is a relatively high probability that the budget of the project will be high. The uncertainty is
even higher when dealing with connected and automated vehicle technologies. To account for the uncertainty, two approaches can be used: sensitivity analyses and risk analyses. A risk analysis approach was selected in this study for implemented in a future version of FITSEVAL to account for the uncertainty in return on investment by expressing the input parameters as probability distributions rather than as fixed values and utilizing Monte Carlo simulation to vary the input parameters and identify probability distributions for each resulting performance measure.

**E.4 FITSEVAL UPDATE**

The original version of FITSEVAL was produced utilizing the Script language of Cube. It works only as a processor to cube provided input and output files, in addition to analyst supplied parameters utilizing the user interface. The new version of FITSEVAL is a standalone desktop tool that reads files from multiple sources as long as it is provided in an acceptable format. The currently acceptable format are Cube files and Highway Capacity Software (HCS) file format. The source of the data can be any model or real-world data as long as it is converted to one of these two formats. The software itself is coded in the C# language. The user does not need to use the C# language to utilize the tool since it is compiled and used in an executable form. The final product is an executable file which could be run on any windows platform. Thus, the user only needs to interface with the tool through the graphical user interface (GUI), input files, and output files. Figure E-1 is an example of the screens of the updated FITSEVAL showing a comparison of the assessed mobility of a corridor with and without connected vehicle (CV)-based adaptive signal control implementation.
Figure E-1: Comparison of Mobility with and without CV –based Adaptive Signal Control

1. INTRODUCTION

1.1 Background Statement

Transportation agencies are increasingly interested in measuring system performance and the impact of advanced technologies and strategies on existing and future year conditions. This interest increased with the MAP-21 and later the Fast-Act federal legislation emphasis on establishing performance goals focusing on seven areas: safety, infrastructure conditions, congestion reduction, system reliability, freight, environmental sustainability, and project delivery time. The federal legislations require states and metropolitan planning organizations (MPOs) to identify performance measures and associated targets and including these targets in the state and MPO plans. For existing conditions, this estimation can be done based on data collected from multiple sources such as statistics office detectors, traffic management system detectors, incident and crash databases, weather agencies, and other sources of data. For future conditions, there is a need to identify models and methods that can be used to support the estimation of system performance. These models will have to be supported by data from multiple sources to ensure their accuracy in estimating future conditions. In 2010, the Florida Department of Transportation (FDOT) sponsored a one-day workshop with staff directors of Florida MPOs on the role of modeling in a performance measurement framework. This workshop was conducted as a step to assist MPOs in the use of travel demand models for developing valid and reliable output to inform a performance-based decision-making process. The objectives of this workshop were to: define performance measures MPOs need the most and provide recommendations to enhance travel demand models and develop analytical tools to evaluate these performance measures. Ideally, such a tool should be able to identify the impacts of conventional improvements as well as advanced strategies and technologies on system performance on the identified measures.

In 2008, the Florida Intelligent Transportation System (ITS) Evaluation (FITSEVAL) tool was developed to estimate the impacts of advanced strategies on system performance. The tool has been used in at least two FDOT districts (Districts 1 and 5). This tool has the potential to be used to forecast system performance with and without technology and strategy deployment and thus support transportation agency investment decisions.

1.2 Goals and Objectives

The goal of this project is to support agencies in measuring and forecasting system performance and the impact of advanced technologies and strategies on existing and future year conditions by taking advantage of state-of-art models, methods, and parameters and available of data from multiple sources. The potential of using a tool as a basis for this support is explored. The outcome of this project will allow a better selection of alternatives for implementation based on combinations of forecasted performance measures that are related to the state and regional goals and objectives. The specific objectives of this project are:
identifying a set of performance measures that can be used as a basis for assessing system performance and comparing improvement alternatives;

• identifying methods to predict performance measures for use in performance and impact assessment;

• identifying FDOT and MPO business processes that can benefit from the utilization of the project development; and

• enhancing and extending existing models in FITSEVAL to allow the assessment of system performance and the impacts of additional advanced and emerging technologies

1.6 Document Organization

This section includes a description of the remaining chapters of this document.

Chapter 2 reviews the experience with FITSEVAL and identifies the agency business processes that are expected to benefit from the developed environment including identifying the range of the business processes and the potential stakeholders of the tool.

Chapter 3 starts with a review of the national and state guidance and practice on performance measurements, and then focuses on the methods and tools for calculating performance measures.

Chapter 4 summarizes different methods to estimate the performance measurement including mobility, reliability, and safety has been described in this chapter.

Chapter 5 describes methods to estimate the impacts of the transportation system management and operations (TSM&O) and ITS applications that are implemented in the updated version of the FITSEVAL tool, produced as part of this project.
2. POTENTIAL TOOL SUPPORT OF BUSINESS PROCESSES

This Chapter first reviews the experience with FITSEVAL. Then, it identifies the agency business processes that are expected to benefit from the developed environment including identifying these processes and the potential stakeholders of the tool.

2.1 FITSEVAL

2.1.1 Review of FITSEVAL

The Florida ITS Evaluation (FITSEVAL) tool is a sketch planning-level Intelligent Transportation System (ITS) evaluation tool that was developed within the Florida Standard Urban Transportation Modeling Structure (FSUTMS)/Cube environment for FDOT by this research team in 2008. (Hadi et al., 2008). This tool can be used to assess the mobility, safety, environmental, and user-cost benefits as well as the costs of various ITS deployment as listed below.

- Ramp Metering
- Incident Management Systems
- Highway Advisory Radio (HAR) and Dynamic Message Signs (DMS)
- Advanced Travel Information Systems (ATIS)
- Managed Lane
- Signal Control
- Emergency Vehicle Signal Preemption
- Smart Work Zone
- Road Weather Information Systems
- Transit Vehicle Signal Preemption
- Transit Security Systems
- Transit Information Systems
- Transit Electronic Payment Systems

The evaluation methodology implemented in the FITSEVAL tool varies with the type of ITS deployments. The output of FITSEVAL includes the impacts of ITS on performance measures including mobility, safety, fuel consumption, emission, and other deployment-specific measures. FITSEVAL also outputs the benefits and costs in dollar values of ITS applications and the resulted benefit/cost ratio. These outputs can be used to assess the ITS deployment, prioritize alternatives, and support plan decisions. In an assessment conducted by the University of Virginia, twelve different existing tools were evaluated and FITSEVAL was recommended for use in Virginia (Ma and Demetsky, 2013).
2.1.2 User Experience with FITSEVAL Tool

2.1.2.1 Application of FITSEVAL in FDOT District 4

To justify the investments, FDOT District 4 traffic management center contracted this research team to evaluate the benefits and costs of a number of ITS components including the Road Ranger service patrol program, Closed Circuit Television (CCTV) camera subsystem, Severe Incident Response Vehicle (SIRV) program, fog warning system, and arterial Dynamic Message Signs (DMS) subsystem. The purpose was to justify to the decision makers in the district, the investment made in these deployments. To accomplish this, the incident management application in FITSEVAL was extended and applied to assess these ITS components. The number of incidents, reduction in incident duration, and diversion rate were updated based on the examination of related databases and interviews with agency personnel. The output of FITSEVAL was used to support the investment decisions of the FDOT D4 Transportation Management Center (TMC).

The original version of FITSEVAL only has a module for the evaluation of dynamic message signs along freeways. To help the FDOT District 4 to evaluate the Arterial Dynamic Message Signs (ADMS) at I-95 and I-75 interchanges in Broward County, FL, a new evaluation methodology for ADMS was developed and implemented in FITSEVAL by this research team in 2011. Similar to the ITS components discussed above, the benefits, costs, and benefit/cost ratio calculated from FITSEVAL were applied by FDOT District 4 TMC to justify the installation of ADMS.

2.1.2.2 FDOT District 5 Experience with FITSEVAL Tool

The FITSEVAL tool was applied to support the short and long range ITS planning of FDOT District Five by Leftwich Consulting Engineering, Inc. in 2016 (Leftwich Consulting Engineers, Inc., 2016a). The travel demand model used in FDOT District Five is the Central Florida Regional Planning Model (CFRPM), while FITSEVAL was originally developed based on Southeast Florida Regional Planning Model (SERPM). The variable naming in these two models is slightly different. Also, the CFRPM model consists of four time periods, that is, the AM, MD, PM, and night periods, while the SERPM model includes three time periods, the AM, PM, and Off-Peak periods. A number of conversions and modifications were first made such that the FITSEVAL tool can be applied to the CFRPM model. Examples include utilizing variable renaming through a conversion function provided with the FITSEVAL tool and creating new network attributes for the off-peak period based on the attributes for the midday and night periods in CFRPM.

In Phase 1 of this project, five Metropolitan Planning Organizations (MPOs)/Transportation Planning Organizations (TPOs) were contacted by the Leftwich Consulting Engineering, Inc. regarding the application of the FITSEVAL tool. As the results of this effort, FITSEVAL tool is recommended to be used as part of MPO/TPO’s planning efforts, for example, long range transportation plan, state of the system annual reports, ITS master plans, and ITS/Congestion Management Plans (CMS)/safety alternative selection and prioritization. Also, based on stakeholder priorities, this study evaluated signal timing improvement strategies for 36 signalized
arterial segments within the regions of the five MPOs/TPOs in FITSEVAL. The results of benefits, costs, and benefit/cost ratios produced by FITSEVAL for these study segments provide reference for MPOs/TPOs to prioritize the signalized corridors for signal retiming. A number of updates to FITSEVAL were recommended by this study, as listed below.

- Have the ability to use existing traffic data
- Further review and enhance emission estimation
- Expand the strategies that can be assessed in FITSEVAL including allowing comparison to roadway capacity improvement.
- Consider corridor characteristics such as turn lanes, driveways, and round-about, and truck characteristics such as passing lanes and truck bypass lanes in the evaluation of signal timing.

Meetings through phone calls or in person were also held by Leftwich Consulting Engineering, Inc. with FDOT Central Office, and FDOT District 5 ITS Operations, Planning, PD&E, and TSM&O staff. These meetings identify the potential usage of FITSEVAL as follows.

- Use of FITSEVAL as a promising platform for individual MPO/TPO to review and prioritize ITS projects.
- FITSEVAL use for congestion management solutions and not only for ITS strategies
- Use of FITSEVAL as part of corridor analyses project as a tool for investigating the application of multi-modal solutions
- Integration of FDOT’s Transportation Value to You (TransValU) spreadsheet, a tool for corridor-level economic and financial analyses for proposed transportation investment in FDOT District 5, with the FITSEVAL tool.

Extensive review of TransValU was conducted by Leftwich Consulting Engineering, Inc. following the stakeholder meeting, but it was determined to keep FITSEVAL and TransValU as separate tools and having FITSEVAL tool to continue to focus on ITS with an integration with the regional demand model.

In Phase 2, Leftwich Consulting Engineers, Inc. (2016b) focused on evaluating the methodologies and parameters used in FITSEVAL for 10 types of ITS deployments and updating them to be consistent with local conditions. A number of default values were recommended to be updated including the parameters for public transportation and emergency vehicle preemption. Instead of considering seven types of signal timing improvements, Leftwich Consulting Engineers, Inc. (2016b) suggested to combine some of the categories and only ask users to select between adaptive controller system and non-adaptive controller system. In addition, a user input of travel time reduction value due to signal timing improvement was proposed to reflect the local experience. It was also decided not to add safety as a benefit for signal timing improvements.

In addition to the original 10 types of ITS deployments, the evaluation methodologies for two new types of deployments were added to FITSEVAL in Phase 2 by Leftwich Consulting Engineers, Inc. (2016b): the first is High-intensity Activated crossWalK (HAWK) that allows pedestrians to safely cross streets, and the second is roadway widening for the purpose of comparison with ITS alternatives. A default reduction of 25% in crashes was assumed for the safety benefits of HAWK. For roadway widening project, the reductions in delay, fuel
consumption and emissions are calculated based on the user input for the percentage increase in congested speed.

Leftwich Consulting Engineers, Inc. (2016b) also examined the base FITSEVAL calculations of safety, fuel consumption, emission, road ranger service patrol benefit, toll, and public transit application benefits in Phase 2. The study updated the default crash rates in FITSEVAL with the segment-based crash rate statistics reported by the Florida Crash Analysis Reporting (CAR) System for the Central Florida Region. With the continuous improvements in fuel efficiency, the study suggested a reduction in fuel consumption rates used in FITSEVAL to account for such improvements. A seven percent reduction for every five mph (Mile Per Hour) was recommended for fuel consumption rate when speed is greater than 60 mph. For emission rates, the study of Leftwich Consulting Engineers, Inc. (2016b) recommended to use the MOVES2014 program emission rate files when they are available. The costs of road ranger service patrol activities were inflated from the year 2008 to year 2016 by applying inflation rates. Since the managed lane post-processing tool, Express Lanes Time of Day (ELToD), have been developed by the Florida Turnpike, no changes were proposed for the managed lane in FITSEVAL since the module was not used. Only one change was made to the transit application benefit, that is, to change the default transit fare from $1.00 to $1.50.

Leftwich Consulting Engineers, Inc. (2016c) updated the costs of each type of deployments based on the cost data from the FDOT District 5 TSM&O Office, the FDOT ITS Maintenance Workload Database, and online literature. An inflation factor was also applied to convert the cost from the year 2008 to year 2016.

2.1.2.3 FDOT District 1 Experience with FITSEVAL Tool

Traf-O-Data Corp (2016) tested the application of FITSEVAL to FDOT District One by coding 10 types of ITS deployments in the District One Regional Planning Model (D1RPM). The review comments are summarized below.

- Applications such as smart work zone and road weather information system are easy to use and seem to provide reasonable results. Environmental sensor stations are recommended to install along roadways with less highway patrol coverage to detect poor weather conditions.
- A number of applications such as incident management and advanced traveler information system are also easy to use but are not useful to District One as dynamic message signs and highway advisory radios are already installed along the major corridors.
- The applications of public transportation and bus priority are not useful for District One as the system has hourly headways.
- The application of signal timing improvement is somewhat difficult to use but it provides reasonable results. Dynamic traffic assignment is recommended to be used for the evaluation of signal timing improvement.
- Managed lane and ramp metering applications are difficult to use as they require a separated loaded network which is not easy to generate. Note that this evaluation is based on the updated version of FITSEVAL by the Citilabs, Inc. in which the evaluation procedure has been changed from the original FITSEVAL version that provides a way to
calculate the delays with ramp metering and managed lanes without re-running the model.
• The application of emergency vehicle preemption is very difficult to use due to the required input that is not easy to obtain, for example, signal cycle length.

2.1.2.4 Virginia Department of Transportation (VDOT) Experience with FITSEVAL Tool

In order to help VDOT and the MPOs in Virginia to make planning decisions regarding the options of operational capacity improvement versus physical capacity expansion, Ma and Demetsky (2013) compared 12 different operational analysis tools for conducting benefit/cost analysis of intelligent transportation systems. Based on the literature review, FITSEVAL was recommended as the operational analysis tool for future sketch planning in Virginia because of its compatibility with the travel demand models in Virginia and also its sophisticated and widely used evaluation methodologies. Two strategies, incident management and managed lanes, were assessed for Hampton Roads area to demonstrate the application of FITSEVAL. The conclusions and recommendations based on the results are:

• The two models of incident management and managed lane can be successfully integrated with the travel demand model, which provides a valuable tool for evaluating operational strategies.
• Some level of manual integration is required during the integration process, including the definition of analysis period(s), facility and area type(s), link capacity, volume-delay function and operational strategy coding. Note that this study used an older version of FITSEVAL. The updated version of FITSEVAL provides a variable conversion function to help the automatic integration between different travel demand models with FITSEVAL.
• A methodology was developed to re-estimate network flows resulting from the implementation of managed lane.
• The default values of the parameters in FITSEVAL are applicable for most of cases.
• Time-of-day modeling is recommended for evaluating operational strategies.
• FITSEVAL should be applied by VDOT’s Transportation Mobility Planning Division and VDOT’s Operations Division as a part of travel demand models to analyze operational strategies. A pilot test in one volunteer district is recommended before wider implementations.
• Existing local data should be collected by Virginia Center for Transportation Innovation and Research (VCTIR) for the application in FITSEVAL.
• VCTIR should continuously work with FDOT on exchanging information regarding needed and developed enhancements to FITSEVAL.

2.2 RELATED FDOT AND MPO BUSINESS PROCESSES

The first step of this project is to examine the business processes of the FDOT, MPO/TPO/TPA, and other partner agencies that can be benefit from FITSEVAL.
2.2.1 FDOT Planning

The FDOT Central Office Planning consists of four divisions: policy planning, system implementation, forecasting and trends, and performance. Below is a list of FDOT planning processes.

**Florida Transportation Plan (FTP):** FTP is the statewide transportation plan that guides the planning and management of Florida transportation system. FTP includes three components: The FTP vision element, the FTP policy element, and the FTP implementation element. The FTP vision element outlines the look of the future Florida transportation system in the next 50 years, while the Florida policy element defines the Florida transportation system for the next 25 years. Developed as a web-based application, the FTP implementation element guides the state, regional, and local transportation agencies in implementing the short-term and medium-term actions and performance measures specified in FTP.

**Strategic Intermodal System (SIS):** SIS is a statewide network that consists of transportation facilities with high priorities for capacity investments such as airport, seaport, rail, waterways, trail, and highways. The establishment of SIS is to enhance the mobility of people and freights and to improve the economy competitiveness of the state. SIS facilities are selected based on the criteria of transportation and economic measures. The FDOT System Implementation Office produces documents of SIS Funding Strategy that identify the potential SIS capacity improvement projects.

**Planning Studies:** Planning studies aim at developing a strategic plan for a SIS corridor or a subarea. The studies examine the existing and future traffic conditions, identify the transportation issues, define the needs, and develop a range of multi-modal alternatives for the study area. Three types of studies are included in these planning studies, that is, corridor, alternative, and feasibility studies.

**Access Management:** Access management balances the accessibility and mobility of roadways by coordinately planning, regulating, and designing access between roadways and their neighboring land development. A permit is required from the FDOT for the access to the state highway systems. Design standard and handbooks such as the median handbook and driveway information guide have been developed by the FDOT as a guidance for access management. This process may require more detailed analysis than the one that can be provided by a sketch planning tool like FITSEVAL.

**Interchange Access Request (IAR):** To minimize the adverse impacts on interstate highway and non-interstate limited access facilities on the state highway system, IAR is required to demonstrate that a new or modified interchange is needed and viable that satisfies the requirements of traffic, environmental, engineering, and funding. An operational and safety analysis needs to be conducted to support such a request. This process may require more detailed analysis than the one that can be provided by a sketch planning tool like FITSEVAL.

**Highway Capacity/Level of Service (LOS):** The LOS has been used as a primary measure of current and future mobility needs. The FDOT sets an acceptable level of service for the planning, design and operation of the state highway system. The target LOS for automobile mode during
peak travel hours is “D” for urbanized areas and “C” for outside urbanized areas. FDOT Quality/Level of Service (Q/LOS) Handbook and accompanying software (LOSPLAN) have been produced to assist the analysis of roadway capacity and quality/level of service for planning and preliminary level analysis. Each FDOT district prepares and maintains the LOS information.

**Project Traffic Forecasting:** Forecast of traffic count, turning movement, and various traffic count adjustment factors are required inputs for Planning and Project Development and Environmental (PD&E) studies and construction plans. Traffic forecasting can be conducted using travel demand model or based on historical trends. A Project Traffic Forecasting Handbook has been developed by FDOT to standardize the practice of traffic forecasting. Tools such as TURNS5 for turning movement analysis and traffic trends analysis tool were also developed to assist traffic forecasting.

**Site Impact Analysis:** Site impact analysis is conducted to examine the traffic-related impacts of new developments. The FDOT develops Transportation Site Impact Handbook and TIPS (Trip Generation, Internal Capture, and Pass-by Software) to guide impact studies. This process may require more detailed analysis than the one that can be provided by a sketch planning tool like FITSEVAL.

**Shared Use Non-motorized (SUN) Trail Network:** Sun trail network is a statewide system that consists of multiuse trails and shared-use paths but physically separated from motorized traffic. The creation of SUN trail network provides alternative travel mode for those origins and destinations with limited access to motorized vehicles. Financially feasible transportation projects on the SUN trail network are listed in the FDOT’s five year adopted work program.

**Statistics, Measures, and Trends:** FDOT tracks the trends of transportation-related statistics and measures. The 2017 FDOT Source book provides a centralized source for these trend information. It covers the trends that affect transportation, for example, demographics, visitor numbers and travel modes, roadway inventory changes, characteristics of vehicle use and seat belt usage, international trade, emissions, and freight growth. The source book also documents the trends of mobility-related performance measures for different types of travel modes. It considers the four dimension of mobility, that is, quantify, quality, accessibility, and utilization.

**Performance Measures:** Performance measures are integrated into three distinct levels of planning and programming process: to establish the goal and objectives at the strategic level, to support funding allocation at the decision-making level, and to monitor project effectiveness and efficiency at the project delivery level. To meet the requirements of MAP-21 and Fast-Act, the FDOT produces Performance Report annually. It covers five aspects of transportation system, including safety, preservation, mobility, economy, and environment, which are connected to the seven focus areas identified by MAP-21. A total number of 14 core measures and 73 supporting measures are reported in the Annual Performance Report.

### 2.2.2 Metropolitan Planning Organization (MPO)/Transportation Planning Organization (TPO)/Transportation Planning Agencies (TPA)

MPOs/TPOs/TPAs are the transportation planning organizations for metropolitan area mandated by the federal government, which develop and maintain the transportation plans that satisfy the
federal requirements and ensure the federal funds for local improvements. Currently, Florida has a total number of 27 MPOs/TPOs/TPAs. Below lists the business processes of MPOs/TPOs/TPAs in Florida.

**Long Range Transportation Plans (LRTP):** Each MPO/TPO/TPA develops a LRTP for a metropolitan area that covers at least a 20-year planning horizon. The LRTP includes both long-range and short-range multimodal-related actions and strategies that address the increasing travel demand. The LRTP developed by each MPO/TPO/TPA should be consistent with the statewide transportation plan. MPO/TPO/TPA is required to review and update the LRTP at least every five years (FDOT Office of Policy Planning, 2018). The latest adopted plan is the 2040 LRTP. A number of MPOs/TPOs/TPAs currently start to work on developing the 2045 LRTP.

**Transportation Improvement Program (TIP):** TIP is a five-year program that reflects the short-term transportation improvement projects with high priorities. Federal law requires TIP to cover a period of four years or more and to be updated every four years. The fifth year of TIP is considered as informational for planning purpose. MPO/TPO/TPA in Florida develops and updates TIP annually.

**Unified Planning Work Program (UPWP):** Each MPO/TPO/TPA in Florida is required to develop a two-year UPWP that identifies the tasks that MPO will perform for the next two years and the associated costs and funding source. When developing UPWP, MPO/TPO/TPA needs to take Federal and State Planning Emphasis Areas (PEA) into consideration. The Florida Planning Emphasis Areas for 2018 is rural transportation planning, transportation performance measures, and ACES (Automated/Connected/Electric/Shared-use) vehicles.

**Public Participation Plan (PPP):** MPO/TPO/TPA develops PPP that explicitly describes how MPO/TPO/TPA involves multi-modal stakeholders, affected public agencies, and individuals into planning process. The effectiveness of PPP is reviewed by MPO/TPO/TPA periodically.

**Congestion Management Process (CMP):** The LRTP focuses on the capital investment solutions over a 20-year horizon, while CMP identifies current and short-term technology-based operational strategies that help reduce single occupancy vehicle travel and facilitates the usage of other modes of transportation such as transit services, community shuttles, bicycles and pedestrians. The CMP provides a standard approach to monitor and evaluate the performance of multimodal transportation system, identify the cause of congestion, identify and assess alternative strategies, identifies and assesses alternative strategies, provide information support for the implementation of actions, and evaluate the effectiveness of implemented actions.

**Bicycle/Pedestrian Program:** Bicycle and pedestrian plan has been developed by a number of MPO/TPO/TPA (e.g., Miami-Dade TPO, and Palm Beach TPA) to identify major bicycle and pedestrian transportation improvements with a purpose of creating safe places for walk and bicycle.

**Freight Program:** The three county MPOs (Miami-Dade, Broward, and Palm Beach Counties) in partnership with FDOT also developed South Florida Regional freight plan.

**Transportation Alternatives Program (TAP):** TAP is a federal fund program that was established by the U.S. DOT to guide the development and growth of the country’s
transportation infrastructure. This program is intended to replace the previous programs such as Transportation Enhancements, Recreational Trials, Safe Routes to School, and several other discretionary program.

**Connected and Autonomous Vehicle Program:** With the advancement in connected and automated vehicles, Miami-Dade TPO is working with partner agencies to plan for the new technologies of connected and autonomous vehicles.

**Performance Measurement Program (PMP):** PMP ensures the investment and policy decisions to satisfy the performance measure requirements specified by MAP-21 for both highway and transit system. It emphasizes the performance-based planning.

**Transportation Disadvantaged (TD) Program:** TD program ensures the availability of cost-effective and efficient transportation services to those persons that are unable to transport themselves or purchase transportation services due to mental or physical disability or because of age or income status.

Table 2-1 Examples of Main Focus Areas for Florida MPO/TPO/TPA’s Business Processes presents some examples of the main focus areas and activities of Florida MPO/TPO/TPA’s business processes. It can be seen from this table that the commonly focused areas for MPOs/TPOs/TPAs are multimodal improvements including transit, bicycle/pedestrian, freight in addition to highways, and congestion management through advanced demand and traffic management strategies. Some emerging areas for MPO/TPO/TPA are autonomous and connected vehicles including the autonomous vehicles for transit and freight, and safety improvements.

### 2.2.3 FDOT Project Development and Environment (PD&E) Studies

Five steps are involved in a typical transportation development process: 1) Long range planning; 2) Project development and environmental (PD&E) study; 3) Design; 4) Right-of-way acquisition; and 5) Construction. As the second step of this process, a PD&E study is conducted to ensure that transportation improvements comply with the requirements of the National Environmental Policy Act (NEPA) or the state requirements regarding environmental impacts. The more detailed steps of the FDOT Project Development and Environmental (PD&E) studies may require more detailed analysis than the one that can be provided by a sketch planning tool like FITSEVAL. More detailed modeling analyses such as those based on data analytics, the highway capacity manual facility procedures, or simulation are needed. During a PD&E study, the location and conceptual design of feasible build alternatives as well as their social, economic, and environmental impacts for transportation improvements are determined. The environmental conditions without build are also documented in the study. A PD&E study is finalized when the environmental documents are reviewed and approved by FHWA or FDOT District Secretary or Delegated Authority. To improve the efficiency of transportation decision making process, the PD&E study can be overlapped with design phase or conducted concurrently.

The Project Development and Environmental (PD&E) Manual developed by FDOT provides a framework for consistent development of transportation projects that comply with federal and state laws and also ensures the uniformity in their quality and exactness. The PD&E manual consists of two parts. Part 1 provides the guidance regarding project development process and required documentations. Part 2 focuses on each topic involved in a PD&E study and associated analysis. Below is a list of those topics and analysis covered in the PD&E manual Part 2.

- **Project description and purpose and need**
- **Traffic analysis**: This includes traffic analysis objectives, level of traffic analysis assessment, performance measures of effectiveness, traffic analysis tool, type and duration of data collection, project traffic forecasting with and without travel demand models, traffic analysis when capacity exceeds traffic demand and vice versa, historical crash analysis and quantitative safety analysis, environmental analyses, and project traffic analysis report.
- **Engineering analysis**: This includes the level of detail of analysis, project coordination, preliminary engineering analysis of existing conditions, alternative analysis (including no-action alternative, TSM&O alternative, multimodal alternatives, and build alternatives), engineering considerations of build alternatives ranging from multimodal impacts and strategies to construction, utility, and storm water management, environmental consideration for build alternatives, comparative alternatives evaluation, value engineering, recommended alternative, and documentation.
- **Sociocultural and aesthetic effects evaluation**
- **Natural resources**: Farmland, publicly owned parks, recreation area, wildlife and waterfowl refuges, wetlands and other surface waters, aquatic preserves and outstanding Florida waters, water quality and water quantity, wild and scenic rivers, floodplains,
coastal zone consistency, coastal barrier resources, protected species and habitat, and essential fish habitat.

- **Cultural resources**: Archaeological and historic resources
- **Physical impacts**: Highway noise, air quality, contamination, utilities and railroads
- **Project commitments and FDOT commitment tracking**

### 2.2.4 FDOT Traffic Engineering and Operations

The mission of FDOT Traffic Engineering and Operations Office is to “improve safety and mobility through the efficient application of traffic engineering principles and practice” (FDOT, 2018a). The implementation of this mission is carried out by providing the following programs and services: traffic services, transportation systems management and operations (TSM&O), Traffic Incident Management (TIM) and Commercial Vehicle Operations (CVO), and traffic system.

**Traffic Services**

The traffic services provided by FDOT Traffic Engineering and Operations Office include traffic studies, intersection operations and safety, signing and pavement marking, signals, and aging road users. Traffic studies are conducted to evaluate transportation system. They typically consist of data collection, traffic volume projection, and identification of improvements for transportation system including intersection and non-intersection roadway segments, signals, and speed zones. A Manual on Uniform Traffic Studies was developed by FDOT to provide minimum standards for conducting traffic studies on the roads managed by FDOT. To improve intersection safety, FDOT focuses on Intersection Control Evaluation (ICE). In an ICE process, intersection control alternatives are quantitatively compared and ranked based on their impacts on operational and safety performance. FDOT is also responsible for providing a uniform system of traffic signal, signs, and pavement marking that comply with the national standards, and improving the safety and mobility of aging road users.

**FDOT Transportation System Management and Operations (TSM&O) Program**

Currently, FDOT TSM&O program focuses on six areas, including connected vehicle, ITS communications, managed lanes, management and deployments, software and architecture, and Statewide Arterial Management Program (STAMP). Below is a brief review of each program.

**Connected Vehicle (CV)**: Connected vehicle is a new FDOT initiative that aims at applying automated and connected vehicle technologies to improve safety and mobility for all modes of travel. Currently, there are one CV project in operation, 10 CV projects in design and implementation, and five CV projects in planning in Florida. Table 2-2 summarizes those 16 CV projects and their focus areas.

</tbody>
</table>

**ITS Communications**: ITS Communications supports telecommunications that are related to ITS deployments and operations. The work conducted by ITS Communications includes: manage, maintain, and update the statewide ITS Wide Area Network, guide the deployment of statewide fiber optic network, manage the statewide radio license database of the Federal Communications Commission, and manage the Wireless General Manager Agreement.

**Managed Lanes**: Managed lane is one of the high priority focus areas for FDOT TSM&O program. FDOT provides statewide guidance and procedures regarding managed lane implementation and operations. An express lane manual is being developed by FDOT Central Office and Florida Turnpike. FDOT is planning to provide additional express lanes that allows travelers to have more mobility choice, more accurate data collection for performance, and better decision making and planning for the future demand.
Management and Deployments: ITS management and deployment program manages the statewide funds on ITS deployments along five principal corridors with limited access in Florida. It provides technical, management, and administrative support to each aspect of ITS projects, including planning, architecture, standards, deployment, integration, operations, maintenance, telecommunication, and mainstreaming.

Software and Architecture: The ITS software and architecture-related functions of FDOT TSM&O program include the management of the statewide ITS Architecture and the SunGuide software, coordinate ITS training, and the unification of traffic information and management system for the statewide ITS traffic data.

Statewide Arterial Management Program (STAMP): The goal of STAMP program is to maximize throughput and provide a safe, reliable, and efficient arterial transportation system. The current focus of this program is to test Adaptive Signal Control Technology (ASCT) and provide guidance regarding the implementation of ASCT.

It should be noted that each FDOT District has its own TSM&O program that customizes the TSM&O concepts and applications to their local needs.

Traffic Incident Management (TIM)/Commercial Vehicle Operations (CVO)

Traffic incident management program explores ways to fast detect and respond to incidents through multi-agency collaborations. It also provides training for incident responders, free road ranger service to assist travelers, and Rapid Incident Scene Clearance (RISC) initiative (an incentive-based program) to help clear major incidents and truck crashes. In addition, as one of Florida’s innovative strategies, Emergency Shoulder Use (ESU) is planned to cover roadway sections along I-4, I-10, and I-75 during major hurricane evacuations.

Commercial vehicle operations cover the activities such as fleet administration and maintenance, commercial vehicle administration, electronic clearance, weight-in-motion, roadside CVO safety, on-board safety monitoring, hazardous material planning and incident response, freight administration, freight in-transit monitoring, and freight terminal management.

Traffic Systems

The FDOT Traffic System division conducts the technical testing and evaluation of transportation devices, develops standards and specifications for all traffic control signals and devices sold or installed in Florida, and manages Florida approved product list.

2.3 EXISTING TOOLS

The section review existing tools, other than FITSEVAL, that have been produced to support the business processes identified in Section 2.2.
2.3.1 SHRP2 L05 Reliability Implementation Guidance

SHRP2 L05 project recommended approaches to incorporate reliability measures into transportation planning and programming processes (FDOT, 2016d). This project recommends that travel time reliability measures to be considered in the following planning and programming products of FDOT. This is an indication that FITSEVAL is a good tool to use for these applications.

- State and metropolitan long-range transportation plan
- Congestion management process
- Studies that examine only portion of transportation system such as corridor, area, and modal studies
- Transportation improvement plan
- Plan for operations or plan for special events, adverse weather and other similar events
- Project development processes such as planning studies, PD&E studies, and design
- Environmental reviews
- Construction and work zone planning
- System operations and management

2.3.2 Recommended FDOT Traffic Analysis Tools

A Transportation Analysis Handbook was developed by FDOT to provide guidance and requirements for a uniform and consistent application of traffic analysis tools in Florida (FDOT System Planning Office, 2014). Within this handbook, a number of traffic analysis tools are summarized for different levels of analysis, as shown in Table 2-3. Table 2-4 lists the traffic analysis software by system element, while Table 2-5 summarized the safety analysis tools.

2.3.3 FDOT District Two Level of Service (LOS) Reporting Tools

The FDOT District Two developed two web-based level of service reporting tools, one for highways, and another one for bicycle and pedestrians, as shown in Figures 2-1 and 2-2. Both LOS reporting tools provide interactive map functions that allow users to configure map layout, search location and attributes, and generate LOS reports. Figure 2-3 shows an example of LOS report generated by the LOS reporting tool. These two LOS reporting tools ease the annual update of LOS.

Figure 2-1 User Interface Snapshot of FDOT District Two LOS Reporting Tool
Figure 2-2 User Interface Snapshot of FDOT District Two Bicycle and Pedestrian LOS

Figure 2-3 Example of LOS Report Generated by the FDOT District Two LOS Reporting Tool
2.3.4 SHRP 2 C11 Post-Processor Tool

The C11 sketch planning post-processor was originally developed by Cambridge Systematics, Inc. to help the Hillsborough County MPO in Tampa, FL, to estimate the safety and travel time reliability performance measures (Cambridge Systematics, Inc., 2016). This tool was further enhanced by implementing more robust technical relationships and re-programming for easy usage through a FDOT SHRP2 implementation assistance project. Figure 2-4 illustrates the basic structure of the C11 post-processor tool (Margiotta and Alden, 2016). As shown in this figure, the required input to the C11 post-processor tool includes crash data and loaded network from travel demand model. In the C11 post-processor, the number of crashes (including total crashes, fatalities, injuries, and PDOs) for each link are calculated based on the Florida-specific safety performance functions. The safety improvements resulted from countermeasures are captured through crash reduction factors recommended by FHWA’s Desk Reference and the CMF Clearinghouse. Different percentiles of travel time index, including 50th percentile, 80th percentile, and 95th percentile travel time index, are calculated as a function of mean travel time index. Such relationships are obtained through a regression analysis over multiple freeway and arterial corridors using the National Performance Management Research Data Set (NPMRDS) data. The mean travel time under normal conditions is derived based on the modified Davidson volume-delay function. The impacts of non-recurrent congestions on delays due to incidents are considered by applying a lookup table for incident-related delays. The costs for operations and ITS strategies are also provided by the C11 post-processor, which can be combined with the improvements in safety and travel time reliability to prioritize projects.

![Figure 2-4 Basic Structure of C11 Post-Processor Tool (Margiotta and Alden, 2016)](image)

2.3.5 Analysis Tools and Methods in Planning for Operations

With the sponsorship of FHWA, Jeannotte et al. (2009) provided recommendation to help planners and operation personnel systematically use existing analysis tools and methods to analyze, assess, and report the benefits of transportation operation improvements. It was mentioned that six methods and tools or their combinations are used in practice by planning and
operation agencies, including sketch planning tools, deterministic models such as HCM procedures, travel demand forecasting models, macro-, meso-, and microscopic simulation tools, archived operations data, operations-oriented performance measures/metrics, and signal optimization tools. Table 2-6 presents transportation planning needs and corresponding operational analysis tools recommended in this brochure. Each of these tools has advantages and disadvantages, as shown in Figure 2-5. Agencies have to select analysis tools based on project characteristics and also available analysis resources and effort. This study identifies the challenge that there are only few established tools and methods for evaluating operational strategies at a regional scale. It also emphasizes the needs of additional guidance on using existing tools and methods for evaluating operations strategies within the planning process.

Table 2-6 Transportation Planning Needs and Operational Analysis Tools (Jeannotte et al., 2009)
Figure 2-5 Advantages and Disadvantages of Operational Analysis Tools (Jeannotte et al., 2009)
2.3.6 Operations Benefit/Cost Analysis Desk Reference

Sallman et al. (2012) developed an Operations Benefit/Cost Analysis Desk Reference for FHWA. This desk reference intends to introduce basic information regarding benefit/cost analysis, and also provide guidance on how to conducting benefit/cost analysis for operational strategies. Table 2-7 summarizes the existing available tools and methods for benefit/cost analysis and Table 2-8 maps these tools to the strategies that can be analyzed using these tools. Among these tools, Tool for Operations Benefit Cost Analysis (TOPS-BC) and SCRITS developed by FHWA and Cal-BC developed by Caltrans are spreadsheet-based sketch-planning benefit/cost analysis methods. These methods rely on generally available input data and apply static default relationship to estimate the impacts, so they provide a quick, simple, and low-cost estimation of benefits and costs. The benefit/cost analysis tools such as IDAS developed by FHWA and FITSEVAL developed for FDOT are post-processor methods that calculate benefits and costs based on travel demand model. These post-processor methods can assess the impacts and measure of effectiveness beyond travel demand model but they require more analysis efforts. In addition, multiresolution and multisenario methods can also be applied for benefit/cost analysis, however, they require much more efforts than the previous two types of methods and tools.

2.3.7 Tool for Operations Benefit Cost Analysis (TOPS-BC)

TOPS-BC is an Excel-based sketch-planning level tool developed by the Federal Highway Administrative (FHWA) Office of Operation to support benefit and cost analysis, as part of the planning for operation initiative (Sallman et al, 2013). Figure 3-6 shows a snapshot of TOPS-BC tool. This tool provides four functions: 1) Investigate the potential impacts of various Transportation System Management and Operations (TSM&O) operation strategies; 2) Recommend evaluation methodology and tools based on use input criteria; 3) Estimate lifecycle costs of different types of deployments including capital cost, replacement cost, and operation and maintenance costs; and 4) Estimate the benefits of particular TSM&O strategies. Below is a list of TSM&O strategies that can be assessed in TOPS-BC.
- Traveler information
  - Dynamic Message Signs (DMS)
  - Highway Advisory Radio (HAR)
  - Pre-Trip travel information
- Traffic signal coordination system
  - Preset timing
  - Traffic actuated
  - Central control
  - Transit signal priority
- Ramp metering systems
  - Central control
  - Traffic actuated
  - Preset timing
- Traffic incident management systems
- Speed harmonization
- Employer based traveler demand management
- Hard shoulder running
- High occupancy toll lanes
- Road weather management
- Work zone
- Supporting strategies
  - Traffic management center
  - Loop detection
  - CCTV

A typical range of impact values are summarized based on literature and recommended to users in this tool. One disadvantage of this tool is that the regional demand model network cannot be directed import to this tool and user has to manually input roadway attributes.
PLANSAFE

PLANSAFE is a tool developed by Washington et al. (2010) to support regional and statewide safety planning efforts. It can be used to forecast the safety impacts of socio-demographic changes and safety countermeasures. Figure 3-7 shows the steps to evaluate safety projects. As shown in this figure, the core of this analysis is to estimate future baseline safety measures using safety performance functions. These safety performance functions include zone-based socio-demographic variables such as population, number of houses per acre, density of k-12 children, number of schools, average household income, and so on. The impacts of safety countermeasures are considered by applying crash reduction factors. However, PLANSAFE framework is not enough to make project level or site level decisions regarding investment.
2.3.9 MOVES

Motor Vehicle Emission Simulator (MOVES) is an emission estimation tool released by the Environmental Protection Agency (EPA). The MOVES model can estimate emissions at three different scales: national, county, and project levels (U.S. Environmental Protection Agency, 2015). The national and county scales are usually used for a large or medium area while the project scale analysis is targeted for small to medium network. The project level is the finest level of vehicle emission estimation in MOVES. It includes three different estimation methods: the average speed approach, the drive schedule approach, and the operating mode distribution.
approach. The average speed approach is the simplest methods of the three approaches. It estimates emissions based on average speed and vehicle mile travelled by vehicle type. This approach can be integrated with various levels of modelling tools to estimate emission by using the link-based performance measures exported from these models as input. The drive schedule method estimates emissions based on second-by-second speed profiles of vehicles. However, this method only allows the input of one representative speed profile from traffic models. The operating mode distribution approach is a detailed emission estimation approach that requires the input of the distribution of each operating mode. Operating modes are defined based on Vehicle-Specific Power (VSP), vehicle speed, and vehicle acceleration. This information can be generated from mesoscopic or microscopic simulation outputs.

2.3.10 MOVES Lite

As MOVES is a computational intensive emission estimation model requiring a large number of data input, Liu and Frey (2013) developed a simplified and light version of MOVES called MOVES Lite. In MOVES Lite, the parameters, such as temperature, humidity, air conditioning load, fuel properties, and so on, are considered to be constant as modeling and simulation scenarios usually represent a short period of time on a typical day. Such an assumption greatly reduces the computation effort required by the full version of MOVES and leads to a simplified estimation of cycle average emission rates for different operating modes. MOVES Lite has implemented in the dynamic traffic assignment tool, DTALite. Figure 3-8 illustrates the vehicle emission rates used in DTALite.

![Figure 2-8 Snapshot of Vehicle Emission Rates Used in DTALite](image-url)
2.3.11 Mobility Needs Assessment Tool (MNAT)

Miami-Dade TPO developed a mobility needs assessment tool (MNAT) to support the transportation needs assessment process (Gannett Fleming, Inc. et al., 2014). It can be applied quickly to assess the mobility impacts of highway and transit improvements for a given corridor without running travel demand model. MNAT is a spreadsheet-based tool. It uses the output of full travel demand model as an initial input, and then estimates the benefits of various capacity improvements such as adding highway lanes, improving operations over existing lanes, and increase transit service in spreadsheets.

2.3.12 Interactive Visualization Tools for Plans

In addition to the previously reviewed analysis tools, interactive visualization tools for various plans, such as long-range transportation plan, transportation improvement plan, strategic plan, and so on, have been used by FDOT and multiple MPOs. These interactive tools not only shows the locations of the projects listed in transportation plans but also provide a description of the project, time frame, costs, and funding agencies. As an example, Figure 3-9 shows the snapshot of the interactive web-based tool for the Metroplan Orlando 2040 long range transportation plan.

Figure 2-9 Snapshot of the Interactive Web-Based Tool for the Metroplan Orlando 2040 LRTP
2.4 Summary of Potential Support of FITSEVAL

This section discusses how FITSEVAL can be updated to better support for planning and planning for operations based on the reviews presented in the previous sections. Table 2-9 summarizes the FDOT and MPO/TPO/TPA business processes and the corresponding potential applications that can be provided by FITSEVAL to support the decisions. It should be noted that only a subset of these potential application will be implemented in the first version of the updated tool produced as part of this project. Additional applications can be implemented in future versions as needed.

</tbody>
</table>

As required by MAP-21 and FAST Act, planning is moving towards a performance-based process. In each transportation plan, performance measures are specified for each goal and objective. These performance measures are related to the safety, mobility, environment, economy, preservation, to collaboration and agency management objectives. The current version of FITSEVAL focuses on mobility, safety, and reliability. FITSEVAL can be upgraded as needed in to estimate performance measures related to other measures and show how these measures satisfy the federal and state requirements.
It is also recommended to update FITSEVAL to allow it to read data from multiple sources to estimate the impacts. As explained in this document, the range of the business processes of the FDOT and MPO/TPO/TPA that can be supported by FITSEVAL range from long range plans that require a very high-level analysis to more detailed analysis required in other business process. Thus, it is recommended that the FITSEVAL is modified to base its analysis on other information sources, in addition to demand model outputs, as is done by the previous versions of FITSEVAL. These additional sources can include real-world data and HCS facility procedure outputs. This could even include mesoscopic and microscopic simulation model outputs in future projects, by writing a translator of the outputs of simulation models to the input file format accepted by FITSEVAL.

Assessing the benefits and costs of transportation alternatives and prioritizing improvement project are important tasks conducted in the planning, planning for operation process, and PD&E studies. 13 ITS strategies can be evaluated in the previous version of FITSEVAL as follows:

- Ramp Metering
- Incident Management Systems
- Highway Advisory Radio (HAR) and Dynamic Message Signs (DMS)
- Advanced Travel Information Systems (ATIS)
- Managed Lane
- Signal Control
- Emergency Vehicle Signal Preemption
- Smart Work Zone
- Road Weather Information Systems
- Transit Vehicle Signal Preemption
- Transit Security Systems
- Transit Information Systems
- Transit Electronic Payment Systems

As new experiences with the 13 ITS strategies become available, the evaluation methodology, parameters, and costs used for these strategies can be updated accordingly. Also, with the emerge of new technologies and management strategies that are being considered or will be considered in planning and planning for operations, new modules can be added to FITSEVAL to assess them. The following additional strategies can be considered in new versions of FITSEVAL.

- Roadway capacity improvement for comparison purpose
- Lane control signals
- Hard shoulder running
- Variable speed limit
- Automated, Connected, Electric, and Shared (ACES) vehicles
- Emergency shoulder running
- Transit-related strategies such as exclusive lanes, bus rapid transit, queue jumper, bus bulb-out, enhanced bus, fare pre-payment, and express transit on managed lanes
- Commercial vehicle information system
• Bicycle facility and sidewalk improvement or dedicated bicycle/pedestrian facilities if bicycle and pedestrian data are available
• Complete street
• Advanced parking system

Based on the analysis in this document, it appears like evaluating signal control, connected, and automated vehicles are high priority areas for transportation agencies in Florida.
3. EXISTING PERFORMANCE FORECASTING AND ASSOCIATED TOOLS

Chapter 2 reviewed the agency business processes that are expected to benefit from the enhancements to FITSEVAL. This chapter starts with a review of the national and state guidance and practice on performance measurements, and then focuses on the methods and tools for calculating performance measures.

3.1 National Guidance and Practice On Performance Measurement

Transportation performance management has been defined by the Federal Highway Administration (FHWA) as “a strategic approach that uses system information to make investment and policy decisions to achieve national performance goals” (FHWA, 2017a). Recently, a strong emphasis has been placed on performance management through federal statutes and regulations. This section provides a detailed review of federal regulations and national experience with performance management.

3.1.1 MAP-21 and FAST Act

The Moving Ahead for Progress in the 21st Century Act (MAP-21) was signed into law in 2012. It aims at creating a performance- and outcome-based surface transportation program. The Fixing America’s Surface Transportation (FAST) Act was built upon MAP-21 and signed in 2015. It provides a long-term funding for surface transportation infrastructure planning and investment. The MAP-21 and FAST Act focus on seven areas. Table 3-1 lists these seven areas and the corresponding national goals. The national highway performance program, metropolitan transportation planning (MPO), and statewide transportation planning are required to consider the national goals and the established performance measures in these focus areas. FHWA has published the final rules for each of the seven areas to establish national performance measures. All the measures except the Greenhouse Gas (GHG) measure was effective on May 20, 2017. On May 31, 2018, the Federal Highway Administration (FHWA) published a final rule that repeals the GHG measure. As such, FHWA will no longer require State DOTs and MPOs to establish targets, calculate their progress toward their selected targets, report to FHWA, and determine a plan of action to make progress toward their selected targets of this measure, if they failed to make significant progress during a performance period.

</tbody>
</table>

A total number of 18 measures as shown in Table 3-2 were specified in the new Code of Federal Regulations (CFR) Title 23 Subchapter E Part 490 (23 CFR Part 490) (Cornell Law School, 2018). Table 3-2 also shows the applicability of these performance measures. State DOTs are required to establish performance target within one year from the effective date of the applicable final rules, and MPOs have 180 days to set their performance targets after the determination of state targets. State DOTs and MPOs need to coordinate with each other as well as public transportation providers when setting those targets. Various plans also require performance targets, including metropolitan transportation plans, metropolitan transportation improvement program (TIP), Statewide Transportation Improvement Program (STIP), state asset management plans under the National Highway Performance Program (NHPP), state performance plans under the Congestion Mitigation and Air Quality Improvement program, and Statewide transportation plans. States are required to report their progress toward achieving performance targets, the condition and performance of the National Highway System (NHS), the effectiveness of investment strategies in the State asset management plan for NHS, and how the state is addressing congestion at freight bottlenecks.

- % of non-SOV travel  
- On-road mobile source emissions  
- Total emission reductions | - All urbanized areas that include NHS mileage and with a population greater than 1 million for the first performance period and with a population greater than 200,000 for the other performance periods and that are at least part of nonattainment or maintenance areas for ozone, CO, PM\(_{10}\), and PM\(_{2.5}\) National Ambient Air Quality Standards. |

The following sessions provide a detailed description of performance measures in each focus area.

#### 3.1.1.1 Safety Performance Measures

The safety performance measures are used by the Highway Safety Improvement Program (HSIP) and for State DOTs to assess serious injuries and fatalities per Vehicle Mile Traveled (VMT) and number of serious injuries and fatalities. The serious injuries are the injuries classified as “A” on the KABCO scale by using the conversion tables developed by National Highway Traffic Safety Administration (NHTSA) before April 15, 2019 and are “suspected serious injury (A)” as identified by the Model Minimum Uniform Crash Criteria (MMUCC) guideline after that (Cornell Law School, 2018). Conversion tables are provided by NHTSA to help state to match the injuries reported by state to the serious injuries as defined above (FHWA, 2017b). As shown in Table 3-2, five safety-related performance measures are established by FHWA, including 1) number of fatalities, 2) number of serious injuries, 3) rate of fatalities per 100 MVMT (Million Vehicle Miles Traveled), 4) rate of serious injuries per 100 MVMT, and 5) number of combined non-motorized fatalities and serious injuries.

Each of these measures is calculated based on a 5-year rolling average. The number of motorized/non-motorized fatalities or serious injuries are calculated by summing the number of fatalities or serious injuries for each of the 5 consecutive years, dividing by 5, and then rounding to the tenth decimal place. The rate of fatalities or serious injuries are calculated by first calculating the number of fatalities or serious injuries per 100 MVMT for each of the 5 consecutive years, averaging these 5 numbers, and rounding it to the thousandth decimal place. It should be noted that the ending year of the 5 consecutive years is the year when the target is calculated.

The numbers of fatalities and serious injuries are obtained from the Fatality Analysis Reporting System (FARS) data. If Final FARS data is not available, the data from FARS Annual Report File (ARF) may be used. The state VMT data is are calculated from the Highway Performance Monitoring System (HPMS) and the MPO VMT is calculated by MPO.
State DOTs are required to establish an annual performance target for each of performance measure for all the public roads within the state and report the targets in the HSIP annual report. The information of the 2018 safety performance targets for each state can be found in the FHWA website (https://safety.fhwa.dot.gov/hsip/spm/state_safety_targets/). In addition to the statewide targets, additional targets can be established for portion of the state. MPOs need to establish performance targets by either agreeing to plan and program projects that help State DOT to achieve the performance targets or defining quantifiable performance targets for the metropolitan planning areas that they represent. State DOTs and MPOs should coordinate with each other to ensure the maximum consistency of the performance targets. The State DOT is required to report the targets to FHWA in the State’s HSIP annual report. The MPOs need to report their targets, baseline safety performance measures, progress toward the targets to the State DOT annually in a way that is specified by both State DOT and MPOs.

The FHWA will evaluate whether a Sate DOT meets the performance targets first at the end of the calendar year after the targets are established and then annually. If at least four out of five safety performance measures met the targets or are better than the measures for the year prior to the establishment of the State’s targets, a State is considered to have met or made significant progress toward the safety performance targets.

### 3.1.1.2 Pavement Condition Performance Measures

As shown in Table 3-2, four national performance measures are specified to assess pavement conditions, that is, percentages of pavements of the interstate system in Good and Poor condition, and percentage of pavements of the non-interstate NHS in Good or Poor condition (Cornell Law School, 2018). In order to calculate these performance measures, State DOTs are required to collect data for the following four condition metrics, International Roughness Index (IRI), rutting, faulting, and cracking percent for pavement. Since the development of this project are not anticipated to deal with these measures, no further discussion of these measures are presented in this document.

### 3.1.1.3 Bridge Condition Performance Measures

According to the final rules in 23 CFR Part 490, two performance measures are used to assess bridge conditions, including percentage of NHS bridges by deck area that classified as in Good condition, and percentage of NHS bridges by deck area classified as in Poor condition by deck area. Since the development of this project are not anticipated to deal with these measures, no further discussion of these measures are presented in this document.

### 3.1.1.4 National Highway System Performance Measures

According to the final rules in 23 CFR Part 490, three performance measures are used to assess National Highway System. Two of them (i.e., percentage of reliable person-miles traveled on the interstate and percentage of reliable person-miles traveled on the non-interstate NHS) are related to travel time reliability and another one is related to the GHG (the GHG measure was later repealed), as shown in Table 3-2. In order to estimate these performance measures, two performance metrics are needed, that is, the Level of Travel Time Reliability (LOTTR) and
annual total tailpipe CO\textsubscript{2} emissions. The LOTTR for each HPMS segment is calculated based on one-year 15-minute travel time data between January 1\textsuperscript{st} and December 31\textsuperscript{st} for all vehicles either from NPMRDS or equivalent data set. The units for travel time is in seconds and the numbers are rounded to the nearest integer. Missing travel time data should not be replaced, and the time periods with road closure are also excluded from the calculation of LOTTR. Four LOTTRs are reported annually for each of four time periods: 6-10am, 10am-4pm, and 4-8pm on weekdays and 6am-8pm on weekends. The LOTTR is calculated as the 80\textsuperscript{th} percentile travel time divided by the 50\textsuperscript{th} percentile travel time and rounded to the nearest hundredth. The travel time reliability measures are calculated using the following expression.

$$100 \times \frac{\sum_{i=1}^{t} SL_{i} \times AV_{i} \times OF_{j}}{\sum_{i=1}^{t} SL_{i} \times AV_{i} \times OF_{j}} = \frac{\sum_{i=1}^{t} SL_{i} \times max TTTR_{i}}{\sum_{i=1}^{t} SL_{i}}$$  (3-1)

where R is the total number of reporting segments with a LOTTR less than 1.5 during all of the four time periods and T is the total number of reporting segments. SL\textsubscript{i} is the length of reporting segment i to the nearest thousandth of a mile. AV is the total annual traffic volume to the nearest single vehicle, which is calculated by Annual Average Daily Traffic (AADT) reported to HPMS in June of the reporting year multiplied by 365 days. OF\textsubscript{j} is occupancy factor for vehicles in a geographic area j. The occupancy factor should be obtained from the latest data tables published by FHWA unless other allowable data sources. The latest value of the average vehicle occupancy factor listed by FHWA (2018c) is 1.7 persons per vehicle for travel time reliability measure.

3.1.1.5 Performance Measure for Freight Movement on the Interstate System

Truck Travel Time Reliability (TTTR) index, which is also referred to as the freight reliability measure, is specified in the final rules of 23 CFR Part 490 to assess freight movement on the interstate system. Truck travel time reliability is defined as 95\textsuperscript{th} percentile travel time divided by normal truck travel time (that is, 50\textsuperscript{th} percentile travel time). The travel time data used for the calculation of TTTR can be obtained from NPMRDS or equivalent data set at 15-minute intervals for each reporting segment specified by the HPMS. The unit for travel time is in seconds. If truck travel times are missing or not reported, they can be replaced by the travel time for all traffic on the roadway during the same 15-minute interval. Also, if a NHS roadway is closed for a certain time period, this time period will not be considered in the calculation of TTTR. TTTR is calculated for five time periods, including 6-10 am, 10am-4pm, and 4-8pm on weekdays from Monday to Friday, 6am-8pm on weekends, and 8pm-6am on all days. The freight reliability measure, TTTR index, is calculated as follows.

$$\frac{\sum_{i=1}^{t} SL_{i} \times max TTTR_{i}}{\sum_{i=1}^{t} SL_{i}}$$  (3-2)

where T is total number of reporting segments and SL\textsubscript{i} is the segment length for segment i. max TTTR\textsubscript{i} is the maximum TTTR of five time periods for reporting segment i. The TTTR index is rounded to the nearest hundredth.
3.1.1.6 Performance Measures for Congestion Mitigation and Air Quality (CMAQ) Improvement Program – Traffic Congestion

Two measures are applied to evaluate traffic congestion based on the final rules in 23 CFR Part 490, including annual hours of Peak Hour Excessive Delay (PHED) per capita and percent of non-SOV travel. The metric of PHED is required to be reported by State DOT by June 15th of each year starting from 2018. In order to calculate PHED metric, a speed threshold is selected by using the value of 20 mph or 60% of the posted speed limit, and the corresponding excessive delay threshold travel time is calculated as follows.

\[
\text{Excessive Delay Threshold Travel Time}_s = \left( \frac{\text{Travel Time Segment Length}_s}{\text{Threshold Speed}_s} \right) \times 3600 \quad (3-3)
\]

where \( s \) refers to a reporting segment.

The delay of a segment (i.e., Road Segment Delay, RSD) is then defined as the difference between the travel time at 15-minute intervals and the above excessive delay threshold travel time. The value of RSD is between 0 and 900 seconds as the maximum delay for a 15-minute calculation interval is 900 seconds. Converting RSD into the units of hour will produce the Excessive Delay measure. The total excessive delay for a one-year period between January 1st and December 31st can be calculated using the following equation.

\[
\text{Total Excessive Delay}_s = \text{AVO} \times \sum_{d=1}^{TD} \sum_{h=1}^{TH} \sum_{b=1}^{TB} (\text{Excessive Delay}_{s,b,h,d} \times \left( \frac{\text{hourly volume}}{4} \right)_{s,h,d}) \quad (3-4)
\]

where TD is total number of reporting days in one year between January 1st and December 31st. TH is total number of hour intervals in a day with only the hours within the peak periods are considered. TB is total number of 15-minute intervals. The 15-minute volume is approximated as the hourly volume divided by 4. AVO is the average vehicle occupancy, which is estimated according to Equation 3-5.

\[
\text{AVO} = (p^C \times \text{AVO}^C) \times (p^B \times \text{AVO}^B) + (p^T \times \text{AVO}^T) \quad (3-5)
\]

where \( p \) refers to the percentage of share of AADT. AVO is average vehicle occupancy. The superscripts C, B, T represent cars, buses and trucks. Table 3-3 lists the latest values of the average vehicle occupancies published by FHWA (FHWA, 2018c). The annual hours of peak hour excessive delay per capita are calculated by summing the total excessive delays for all the reporting segments and divided by total population published by the U. S. Census, as shown in Equation 3-6.

\[
\text{Annual Hours of Peak Hour Excessive Delay per Capita} = \frac{\sum_{d=1}^{T} \text{Total Excessive Delay}_s}{\text{Total Population}} \quad (3-6)
\]

Three methods can be applied to calculate the “percentage of non-SOV travel” measure. Method A relies on the American Community Survey and the percentage of non-SOV travel is calculated as 100% minus the percentage of SOV including cars, trucks, or vans. Method B is based on a local survey. Method C obtains this measure based on system use measurement by dividing the annual volume of person travel other than driving alone by the summation of annual volume of
person travel while driving alone and other than driving alone. The resulted percentage of non-SOV travel is rounded to the nearest tenth of a percent.

3.1.1.7 Performance Measures for CMAQ Improvement Program – On-Road Mobile Source Emissions

Based on the final rules in 23 CFR Part 490, the performance measure to assess on-road mobile source emissions is total emissions reductions, which are calculated as the cumulative 2-year and 4-year emissions reductions for all projects funded by CMAQ funds for each pollutant of Nitrogen Oxide (NOx), Volatile Organic Compounds (VOCs), Carbon Monoxide (CO), and particulate matter (PM2.5 and PM10) with designated nonattainment or maintenance areas. The emission reduction data comes from the CMAQ Public Access System.
3.1.2 Transportation Performance Management (TPM) Guidebook

A TPM guidebook developed by FHWA provides a comprehensive view of transportation performance management principles and can be applied to assist agencies in implementing performance-based planning and programming (FHWA, 2018d). Figure 3-1 shows the ten components of TPM framework that are discussed in this guidebook, including

- Strategic direction
- Target setting
- Performance-based planning
- Performance-based programming
- Monitoring and adjustment
- Reporting and communication
- Performance management organization and culture
- External collaboration and coordination
- Data management
- Data usability and analysis

A detailed description of definitions, principles, classifying terminology, relationship to TPM components, regulatory resources, assessing risks, and implementation steps is provided to each of TPM component.

![Figure 3-1 TPM Framework (Source: FHWA TPM Guidebook (FHWA, 2018d))](image)

Chapter 2 of the TPM Guidebook provides examples of analytical tools and methods that agencies can use to forecast future performance, which is summarized in Table 3-4.
<table>
<thead>
<tr>

<th>Tools and Methods</th>
</tr>
</thead>
</table>
| Bridge            | • Bridge Management software (BrM) (formerly Pontis)  
• Deterioration models to predict future bridge condition based on past data and bridge age  
• Algorithms to process National Bridge Inventory (NBI) and Element data to establish targets  
• Forecasting tool that combines historic performance and historical funding level then predicts expected condition using expected funding target for the bridge program  
• Full life cycle (75 year) analysis of bridge condition combined with revenue projections and construction inflations used to maximize the investment’s impact on bridge assets  
• A deficit report based upon current investment and condition compared with future investment |
| Pavement          | • Pavement Management System (PMS): model future pavement conditions on a set of criteria such as traffic levels, asset type, age of pavement, and resource constraints  
• GIS for data analysis and visualization  
• Business Intelligence and visualization tools  
• The graph that shows the predicted pavement performance versus age from 2012 Pavement Condition Report |
| Safety            | • Linear regression, rolling averages, best-fit regression analysis, non-linear regression, time-series analysis  
• Safety trend line based on 5-year and 10-year rolling average and superimposed with safety target (for example, the safety trend line for the Washington State Department of Transportation (WSDOT) fatality forecasting through 2030) |
| System Performance| • Travel demand models  
• Highway Capacity Manual  
• System transportation performance management systems  
• Model estimating the economic benefits infrastructure improvements (e.g., Highway Economic Requirement System (HERS), Transportation Economic Development Impact System (TREDIS))  
• National Emissions Inventory (NEI), Air Quality System (AQS) and Mobile 6.2 |
3.1.3 Performance Measures ATDM Recommended by FHWA

A set of performance measures (also referred to as measure of effectiveness) was recommended by FHWA to capture the impacts of Active Transportation and Demand Management (ATDM) strategies on travel and congestion (Dowling et al., 2013). Table 3-5 lists those performance measures and estimation methods.

Table 3-5 Performance Measures Recommended by FHWA to Quantify the Effectiveness of ATDM (FHWA, 2013)

3.2 Florida Statewide Guidance and Practices

This section provides a detailed review of FDOT and MPO guidance and practice on performance measurements.

3.2.1 FDOT Annual Performance Report

The FDOT Performance Program publishes performance report each year. The latest performance report covers five areas, including safety, preservation, mobility, economy, and environment (FDOT, 2016a). Figures 3-2 to 3-6 list the FTP goal, objectives, and related performance measures for each focus area. As shown in these figures, a set of core measures as well as supporting measures are listed for each focus area. These measures are reported for a time period that spans for the past 10 years if data is available. The data sources are from different FDOT offices (for example, FDOT Safety Office, FDOT Office of Maintenance, FDOT
State Traffic Engineering Operations Office, etc.) and the previous statewide reports. The corresponding performance targets and a list of improvement strategies are also included in the performance report. The FDOT’s performance report also recommends potential measures that can be included into the future performance report. Below is a brief list of these potential measures:

- **Safety**
  - Complete street-related safety measures
  - Transit performance-related safety measures
  - Pedestrian/bicycle related safety measures

- **Preservation**
  - Consideration of vehicle condition and average fleet age for transit performance measures
  - Bicycle and pedestrian facility that facilitates access to transit
  - Bicycle and pedestrian facility maintenance measures
  - Percent system at risk/retrofitted for resiliency

- **Mobility**
  - Measures for bicycle and pedestrian program impacts
  - Customer stratification and usage measures for bicycle/pedestrian network
  - ITS coverage of system
  - Automated vehicle technology usage measure
  - Average transit load factors
  - Transit access measures
  - Measure for extent of telecommuting over time
  - Measures for the benefits of complete streets

- **Economy**
  - Number of transportation technology companies located in Florida and doing business
  - Travel time by mode
  - Delivery time trends
  - Shipping cost trends
  - Transportation sector job growth
  - DEO and Florida Chamber Economic
  - Connectivity measures including cost and time savings
  - Expanded and improved Strategic Intermodal System (SIS) investments
  - Freight bottlenecks reduction

- **Environment**
  - Measures for community values and transportation preferences
  - Standard walkable index
  - Commuting time and costs
  - Percent of trips that are pedestrian and bicycles
  - Percent of electric vehicles and autonomous vehicles
  - Percent of people that drive alone
  - Measures for quality places in terms of transportation

3.2.2 FDOT TSM&O Strategic Plan

The 2017 FDOT Transportation Systems Management & Operations (TSM&O) Strategic Plan sets three types of TSM&O program goals. These include the goals applied to on-going operation and maintenance (O&M) performance of TSM&O system and strategies, the performance enhancement goals for the O&M of system that hasn’t reached the goals, and the project performance enhancement goals for outcomes of planned and future implemented TSM&O strategies and projects. Seven goals were specified for the on-going TSM&O system performance measures covering mobility, safety, and ITS/communication networks maintenance. Table 3-6 summarizes these goals, the corresponding performance measures for each of the goals, and the associated data source. Table 3-7 lists the outcome performance metrics and goals for the planned FDOT TSM&O strategies.

Notes:
* NA means not available.
Appendix A of the TSM&O strategic plan provides a TSM&O strategy toolbox, which includes the definitions, performance metrics, and references for more than 50 TSM&O strategies or tools. Table 3-8 summarizes the performance metrics for the TSM&O strategies in this toolbox. As shown in this table, three categories of performance measures are commonly used to assess TSM&O strategies, that is, (1) safety measures of crash and secondary crashes; (2) mobility measures in terms of travel time, travel time reliability, and throughput; and (3) measures of system and agency efficiency.

The Regional Integrated Transportation Information System (RITIS) collects real-time point traffic detector data as well as real-time traffic data from a third party private sector vendor. It reports a set of performance measures, which are also introduced in the FDOT 2017 TSM&O strategic plan, as shown in Table 3-9.

#### 3.2.3 Florida Multimodal Mobility Performance Measures Source Book

The FDOT Transportation Statistics Office produced a multimodal mobility performance measures source book annually, which reports historical and current mobility performance measures results for state highway system including the strategic intermodal system (FDOT, 2016b). Four dimensions of mobility are considered, which are quantity, quality, accessibility, and utilization. Table 3-10 Multimodal Mobility Performance Measures Matrix (FDOT, 2016b) summarizes the performance measures included in this source book.

3.2.4 Florida MPO Handbook

One of the chapters in the FDOT MPO Handbook is performance management (FDOT, 2018b). In this chapter, a national transportation performance management framework as well as the national policies on state and MPO performance management are presented. States, MPOs, and public transportation providers must establish performance target for each performance measure identified by the final rules of the USDOT, reviewed earlier in Section 2 of this document. MPOs must include a description of the performance measures and targets in a Long Range Transportation Plan (LRTP). A system performance report is also required to be included in a LRTP to be compared with the system performance in the previous reporting period or baseline data. When MPOs develop multiple scenarios while preparing for LRTP, a system performance is also needed to demonstrate how the preferred scenario can help move toward the performance targets. Similarly, Transportation Improvement Program (TIP) is required to be designed such that when it is implemented, it can help achieve the performance targets. TIP also needs to document such anticipated impacts. In addition to the above requirement, MPOs are also required to coordinate with state and public transportation providers to ensure the MPOs’ performance measures and targets are consistent with state and public transportation providers’ plans. When developing LRTP and TIP, the states and MPOs need to meet the performance-based planning and programing requirements no later than two years from the effective date of each performance measure rule or two years from the publication date of planning rule on May 27, 2016.

3.2.5 MPO/TPO/TPA Practice on Performance Measures

This section discusses how performance measures are used in the business processes of metropolitan planning organization/transportation planning organization/transportation planning agency (MPO/TPO/TPA).

3.2.5.1 FDOT/MPO Pilot for National Performance Measures

As a FDOT’s pilot effort to collaborate with MPO on performance measures, national performance measures for four MPOs (including Hillsborough MPO, Broward MPO, Gainesville MTPO, and India River County MPO) were calculated and added to the FDOT statewide annual performance measure report (FDOT, 2016c). The MAP 21 performance measures that have been calculated and not calculated in this pilot are shown in Figure 3-7. It is seen from this figure, the only measures that were not calculated are the ones for pavement conditions. The measure of peak hour travel reliability in this effort was calculated as the percentage of freeway trips traveling at greater than or equal to 5 mph below the posted speed limit except that a threshold of 45 mph was used for seven counties. Since this effort was conducted in 2016, this measure is different from the measure of level of travel time reliability (defined as 80th percentile travel time index) specified in the final rules of MAP-21 performance measures. In addition, two FDOT mobility measures were also calculated for these four MPOs, including the percentage of heavily congested freeway miles at the peak hour and daily hours of vehicle delay.
3.2.5.2 Miami-Dade TPO

**Long Range Transportation Plan (LRTP)**

Based on the national and state goals, eight goals were proposed for the Miami-Dade 2040 Long Range Transportation Plan (LRTP) to maintain the County’s status as a top-100 global city, to improve the County’s transportation system, and to meet the transportation service needs with the expected growth of travel demand (Gannett Fleming, Inc. et al., 2014). A weight was given to each of these goals based on the ballots collected from 15 community workshops and meetings. Below is the list of those eight goals. The number in the bracket is the corresponding weight.

- Improve system and travel (25%)
- Improve safety (8%)
- Improve security (3%)
- Support economic vitality (12%)
- Preserve environment and quality of life (14%)
- Improve connectivity (14%)
- Employ sound investment strategies (12%)
- Preserve the existing system (12%)

To achieve the eight goals, 63 objectives were developed and a total number of 89 system measures were identified correspondingly. Table 3-11 lists these goals, objectives, and performance measures.

The identified performance measures are divided into two groups based on the scope of performance measurements: system-level performance measures and project-level performance measures. System-level performance measures assess the County’s transportation system as a whole and were applied to four system-level scenarios, including base year 2010, existing-plus-
committed 2019, needs plan 2040, and cost-feasible plan 2014. Project-level measures are used to prioritize improvement projects during the development of a cost feasible plan. The evaluation of each needs plan project was conducted using three steps: goal elements analysis, congestion coordination, and implementing agency coordination. In the step of goal elements analysis, the proposed improvements for each project were matched to the specific elements of the goals and objectives of the 2040 LRTP. Table 3-12 lists the goal elements and the corresponding performance measures. Two types of performance measures are included in this list. The first is geographical elements that can be assessed using buffer analysis in Geographic Information System (GIS). The second involves qualitative measures which are evaluated by scores. A weighted score was calculated for each project by summing up the scores for all the goal elements.

<td><strong>Objective 7.5</strong> Promote local improvement projects within the systems improvement context</td>
<td>Number of improvements on local facilities (non-State Highway System)</td>
</tr>
<tr>
<td><strong>Objective 7.6</strong> County will establish strong regional linkages with Southeast Florida governments to plan for infrastructure</td>
<td>Does the plan address regional intergovernmental coordination?</td>
</tr>
</tbody>
</table>

| **Goal 8 - Maximize and Preserve the Existing Transportation System**      |                                                                          |
| **Objective 8.1** Continue to examine the provision and utilization of managed lanes on the existing system | Lane miles of managed lanes as a proportion of total lane mile improvements. |
| **Objective 8.2** Identify and implement the best available technologies and innovations to improve the reliability and efficiency of the transportation system | Transit route miles on managed lanes |
| **Objective 8.3** Identify and reserve corridors and right-of-way (on roadways, railways, and waterways) for future transportation facilities and services | Does the plan identify and consider the latest technologies and innovations in transportation improvements? |
| **Objective 8.4** Expand the use of Transportation Demand Management (TDM) strategies | Does the plan identify and consider right of way acquisitions as a phase that can be planned independently? |
| **Objective 8.5** Achieve and maintain a state of good repair for transportation assets for all modes | Number of projects which utilize TDM strategies. |
| **Objective 8.6** Reduce the vulnerability and increase the resilience of critical infrastructure to the impacts of climate trends and events | Percent of funding allocated to maintenance and rehabilitation. |
| **Objective 8.7** Minimize damage to infrastructure from transportation vehicles | Highway lane and centrelane miles within the 100-year flood plain. |
| **Objective 8.8** Ensure necessary supporting infrastructure (water, sewer, drainage) capacity is available for new projects and improvements. | Local centerline and lane miles of roadway with high truck volumes. |
| **Objective 8.9** Repair and maintain existing infrastructure first | Does the plan consider existing utilities infrastructure when planning new projects? |
| **Objective 8.10** Achieve and maintain a state of good repair for evacuation corridors | Does the plan prioritize repair and rehabilitation of existing infrastructure before construction of new infrastructure? |
|                                                                          | Percent of funding allocated to maintenance and rehabilitation of evacuation corridors. |

**Performance Management Program (PMP)**

The Performance Management Program (PMP) of the Miami-Dade TPO follows the performance measure requirements specified by the USDOT and the State. The highway-performance measures that are considered by the PMP are related to the seven focus areas of the MAP-21 and FAST Act. The transit performance measures used by the PMP are based on the requirement of Transit Asset Management (TAM) (49 USC 5626), which are listed below.

- Percentage of non-revenue, supporting-service and maintenance vehicles that have either met or exceeded their useful life benchmark (ULB).
- Percentage of revenue vehicles within a particular asset class that have either met or exceeded their ULB.
- Percentage of track segments with performance restrictions for rail fixed-guideway, track, signals, and systems.
- Percentage of facilities within an asset class with a rating below condition 3 on the Transit Economic Requirements Model (TERM) scale.

**Bicycle/Pedestrian Plan**

Five goals and 31 objectives were identified in the Miami-Dade 2040 Bicycle/Pedestrian Plan (Kimley-Horn and Associates, Inc., 2013). Bicycle Level of Service (BLOS) and Pedestrian Level of Service (PLOS) were used as main performance measures to check the performance of bicycle and pedestrian travel on a given roadway network, respectively. The methods to calculate the BLOS and PLOS are based on the FDOT Quality/Level of Service (QLOS) Handbook. The BLOS is calculated as follows.

\[
BLOS = 0.507 \ln \left( \frac{Vol_{15}}{L} \right) + 0.199SP_t(1 + 10.38HV)^2 + 7.066(1/PR_5)^2 - 0.005(W_e)^2 + 0.76
\]

where \( Vol_{15} \) is motorized vehicle directional volume in the peak 15-minute time period, \( L \) is number of through lanes, \( HV \) is percentage of heavy vehicles, \( PR_5 \) is the FHWA’s five-point pavement surface condition rating, \( W_e \) represents the average effective width of the outside through lane, \( SP_t \) is an effective speed factor, which is defined as

\[
SP_t = 1.1199 \ln(SP_p - 20) + 0.81036
\]

where \( SP_p \) is posted speed limit as a surrogate for the average running speed.

Equation 3-9 gives the expression for the calculation of PLOS.

\[
PLOS = -1.2276 \ln(W_{ol} + W_l + f_p \times %OSP + f_b \times W_b + f_{SW} \times W_s) + 0.0091 \left( \frac{Vol_{15}}{L} \right) + 0.0004SPD^2 + 06.048
\]

where \( W_{ol} \) is the width of outside lane, \( W_l \) is the width of shoulder or bicycle lane, \( f_p \) is On-street parking effect coefficient with a default value of 0.20. %OSP represents the percent of segment with occupied on-street parking. \( f_b \) is the buffer area barrier coefficient. The value of \( f_b \) is 5.37 for trees spaced 20 feet on center. \( W_b \) is the buffer width in feet, which is the distance between
the edge of pavement and sidewalk. fsw is sidewalk presence coefficient, which is calculated as the difference between 6 and the sidewalk width multiplied by -0.3. SPD is the average running speed of the motorized vehicles traffic.

The safety-related performance measures used in the Miami-Dade 2040 Bicycle/Pedestrian Plan include the number of bicycle-related crashes per square mile, the number of pedestrian-related crashes per square mile, and the number of pedestrian or bicyclists injuries and fatalities for the past 12 years. The time period of 12 years was used because of data availability.

3.2.5.3 Broward County MPO

LRTP

The 2040 LRTP by Broward County MPO identified six strategic areas, including bicycle/pedestrian, public transportation, car, freight, air, and sea (Broward MPO, 2013). Three goals with measurable objectives were proposed for these areas, as shown in Table 3-13 to Table 3-15. The measures in these three tables can be classified either as objective measures based on facts or subjective measures depending on opinions.

Table 3-13 Objectives and Measures of Effectiveness for the Goal of Moving People in the Broward County 2040 LRTP (Broward MPO, 2013)

<table>
<thead>
<tr>
<th>Objective</th>
<th>How Objective is Achieved (Measures of Effectiveness)</th>
</tr>
</thead>
</table>
| Maintain infrastructure | • All operating and maintenance costs for existing facilities/services are fully funded through existing revenue sources (objective) for the life of the project/service or for the duration of the cost affordable plan, whichever comes first.  
• All operating and maintenance costs for proposed facilities are funded through existing (objective) and/or reasonably expected future revenue sources (subjective). |
| Achieve LOS standards on existing infrastructure | • Maximize the proportion of facilities by mode operating at or exceeding Level-of-Service (LOS) standards weighted by the number of users or adjacent populations (objective). |
| Improve accessibility for all users of the transportation system | • Maximize the number of jobs within 30 minutes travel time by mode  
• Maximize the number of facilities that are consistent in lanes, technology and policy (such as pricing, pedestrian only, bicyclist only, etc.) across county lines. |
| Shorten Project Delivery | • Minimize the number of projects that need new rights-of-way (ROW). |
| Maximize Transit Ridership | • Increase transit mode share by 20% (build share / baseline share) in all planning sectors  
• Increase transit mode share by 40% (build share / baseline share) in all areas with 20,000 or more persons per square mile  
• Increase transit mode share by 40% (build share / baseline share) in all areas with 10,000 or more employees per square mile |
Table 3-14 Objectives and Measures of Effectiveness for the Goal of Creating Jobs in the Broward County 2040 LRTP ((Broward MPO, 2013))

<table>
<thead>
<tr>
<th>Objective</th>
<th>How Objective is Achieved (Measures of Effectiveness)</th>
</tr>
</thead>
</table>
| Maintain or reduce average travel time to major economic centers of the urban area | • Average travel time to Central Business Districts (CBDs), outlying business districts and major employment centers with more than 5,000 employees/square mile (No Build Alternative – Build Alternative) for all modes  
• Average in-vehicle travel time to Port Everglades (No Build Alternative – Build Alternative)  
• Average in-vehicle travel time to Fort Lauderdale/ Hollywood International Airport (No Build Alternative – Build Alternative) |
| Promote new development                                                   | • Provide newly developing areas frequent transit service (20 minute or less headway) or 95% of highway lane miles in developing areas at Level-of-Service (LOS) C or better |
| Minimize the overall cost of travel                                      | • (Travel time * value of time + operating cost + maintenance cost) / (person miles of travel + truck miles of travel). |
| Maximize private investments in transportation service provision         | • Minimize net cost of public expenditures in project development  
• Increase community / public involvement via innovative approaches |

Table 3-15 Objectives and Measures of Effectiveness for the Goal of Strengthening Communities in the Broward County 2040 LRTP ((Broward MPO, 2013))

<table>
<thead>
<tr>
<th>Objective</th>
<th>How Objective is Achieved (Measures of Effectiveness)</th>
</tr>
</thead>
</table>
| Insure transportation benefits and costs are equitably distributed throughout the region | • Maximize the number of viable transportation alternatives in all 5 of the MPO's geographic planning areas  
• Improve accessibility to employment opportunities in areas of the county where the majority of residents make 50% or less of the median income |
| Reduce accidents, injuries and fatalities                                 | • Redesign major accident locations                                                                                   |
| Promote redevelopment and infill                                         | • Maximize Public Private Partnership development opportunities in areas of the county where the majority of residents make 50% or less of the median income  
• Increase premium transit access to jobs and population |
| Insure projects include appropriate aesthetic considerations in their project design | • Project budget must have a line item for aesthetic improvements                                                     |
| Provide options for non-motorized travel                                 | • Number of miles of sidewalk/number of roadway miles (coverage)  
• Number of bicycle lane miles/number of roadway miles (coverage)  
• Minimize the number of gaps in the sidewalk and bike lane network                                                      |
| Promote environmentally sensitive projects                               | • Reduce energy consumption measured as British Thermal Unit of Energy consumed (BTU)/person mile traveled  
• Produce less tons of ozone precursors and greenhouse gasses (CO2) than were produced in 1990 (pre Clean Air Act Amendments). |
Unified Planning Work Program (UPWP)

Even though no specific performance measures have been mentioned in the Broward UPWP (Broward MPO, 2018a), the Broward UPWP listed the FDOT District 4 performance measurement/management-related activities in financial years 2018 to 2020, which include:

- Provide technical support to implement the performance-based planning and programming required by MAP-21 and Fast Act.
- Participate in the FDOT Mobility Performance Measures (MPM) program and maintain a district-level MPM program that address all modes.
- Focus on the use of performance measures by performing research, sharing information, and supporting collaboration.
- Share knowledge of quality/LOS and other performance measures that agencies are currently use in their comprehensive plans.

Performance Measurement Program (PMP)

A performance measurement framework was developed by the Broward MPO in 2015 and was used to assess the baseline performances of the Broward region’s transportation system (Broward MPO, 2015a). The development of such a framework considered the following factors:

- Broward MPO leadership focus
- New state and metropolitan performance-based planning requirements
- New national performance measures program
- FDOT performance measurement activities
- Industry-wide adoption of performance practices

Based on the above factors, five sets of performance measures were proposed, which correspond to the five primary performance areas: mobility, connectivity and accessibility, asset management, safety, and project delivery. A performance scorecard was also created according to those measures as illustrated in Table 3-16. As shown in this table, the performance measures focus on not only vehicles but also multimodal transportations.

Congestion Management Process/Livability Planning

Congestion management aims at developing and implementing non-road widening strategies to improve road user safety and mobility while encouraging multimode transportation usage (Broward MPO, 2015b). The congestion management corridor/area studies are part of the congestion management process. Table 3-17 illustrates the project-level objectives and performance measures for the Hollywood/Pines Corridor study. The monitoring measures were applied to reflect how the project helps achieve the goals specified in the Broward LRTP.
Table 3-16 Performance Scorecard ((Broward MPO, 2015a))

**Mobility Hub Program**

An evaluation framework was developed for mobility hub programs in the Broward 2035 LRTP. However, in the Broward 2040 LRTP, the mobility hub initiatives were not directly addressed but indirectly related to the goals (Broward MPO, 2018b). To reflect the current priorities of the Broward MPO for mobility hubs, a new methodology was developed by the Broward MPO, which is shown in Table 3-18.

**Table 3-18 Mobility Hub Market and Network Readiness Criteria (Broward MPO, 2018b)**

**Complete Streets**

Complete streets have been one of the most important focus areas for the Broward MPO. An evaluation framework as well as a toolkit were developed to assist the assessment of complete streets initiatives (Broward MPO, 2015c). The evaluation of complete streets can be conducted at two levels, corridor-level and program-level. Tables 3-19 and 3-20 present the goals, objectives, metrics, performance measures, and corresponding tools for corridor-level and program-level evaluation of complete streets, respectively.

3.2.5.4 Palm Beach County MPO

**LRTP**

Five goals and nineteen objectives were created in the Palm Beach 2040 LRTP (Palm Beach MPO, 2017a). The performance measures are included as a part of the objectives of the Palm Beach 2040 LRTP, as shown in Table 3-21. It can also be seen in this table that the goals focus on multimodal transportations. The current values of those performance measures and the target values for year 2025 and 2040 are also clearly specified in this table. Based on the values in Table 3-16, a scoring procedure was developed to prioritize the desired projects listed in the 2040 LRTP, which is shown in Table 3-22.

In the Palm Beach 2040 LRTP, the future population in year 2040 was forecasted based on the controlled total population retrieved from the Bureau of Economic and Business Research (BEBR). A tool, Population Allocation Model, was used to distribute the controlled total population to each individual traffic analysis zone. The growth rate of population was then applied to employment data to predict the employment in year 2040 with the consideration of land use. The predicted values of population and employment were used as the input values to travel demand model to study the impacts of improvements.

The details of how the performance measures listed in Table 3-21 are calculated and the associated data sources can be found in the document of Palm Beach MPO Congestion Management Process (CMP) (Palm Beach MPO, 2016a). Figure 3-8 shows an example of the Palm Beach MPO CMP annual reporting card.

Note: The procedure was utilized for the Directions 2040 Plan. It is not an adopted procedure and it may be updated regularly as part of the MPO's annual revenue allocation process.
Figure 3-8 Example of Palm Beach Congestion Management Process Annual Report Card (Source: Palm Beach County MPO, 2016b)
**5-Year Strategic Plan**

A 5-year strategic plan has been established by the Palm Beach MPO to be used as a guide toward achieving long-term vision and missions (Palm Beach MPO, 2017b). Aligned with the Unified Planning Work Program (UPWP), six goals were formed in this strategic plan, including:

- Administer the agency
- Engage the public
- Plan the system
- Prioritize funding
- Improve the experience
- Collaborate with partners

The associated objectives and performance measures were identified for each goal. It should be pointed out that targets were also specified for each performance measure. An annual report card was developed to monitor the progress to achieve the goals. Figure 3-9 shows an example of such an annual report card.
### HOW ARE WE DOING?

Monitoring and annual reporting of timely progress toward the objectives informs (1) administrative decisions and actions by the Executive Director and (2) future MPO Governing Board decisions regarding appropriate revisions to investments in and additions to the Strategic Plan. This “report card” is a summary of the MPO’s current status in relation to achieving each goal’s set of objectives.

Figure 3-9 Example of Palm Beach MPO Strategic Plan Annual Report Card (Source: Palm Beach County MPO, 2017b)
**Pedestrian and Bicycle Safety Study**

The Palm Beach MPO Pedestrian and Bicycle Safety Study provides a list of countermeasures to reduce pedestrian and bicycle-related crashes (Kimley-Horn and Associates, Inc. 2017). In this document, the data sources for safety analysis include:

- Strava for pedestrian and cyclist information
- Florida Department of Health’s (FDOH) Florida Injury Surveillance Data System
- Florida Department of Highway Safety and Motor Vehicles (DHSMV) Traffic Crash Facts Annual Report
- Palm Beach County crash system data
- Florida Department of Transportation (FDOT) Unified Basemap Repository (UBR) data

The performance measures used are number of pedestrian/bicyclist fatalities or injuries by different categories, for example, year, month, day of week, time of day, lighting conditions, road surface condition, weather condition, age, etc.

**US-1 Multimodal Corridor Study**

Different from the traditional transportation studies, the US-1 multimodal corridor study utilized a Health Impact Assessment (HIA) evaluation procedure (Palm Beach TPA, 2018). This procedure consists of six steps: screening, scoping, assessment, recommendations, reporting, and monitoring and evaluation. It considered the impacts of proposed project on the health of a population and the distribution of these impacts within the population. Table 3-23 lists the performance indicators used in the HIA evaluation process.

An updated congestion management process was included in the MetroPlan Orlando 2040 LRTP (MetroPlan Orlando, 2016a). Figure 3-10 illustrates the steps used in the congestion.
management process. As shown in this figure, the process consists of eight steps and the third step is to develop multimodal performance measures. Figure 3-11 shows the relationship between CMP performance measures and the identified objectives. It can be seen from this figure that the CMP performance measures cover the areas of mobility, safety, reliability, transit ridership and performance, shared ridership, bicycle/pedestrian facilities, signal retiming benefit/cost, and so on.

Figure 3-10 Congestion Management Process (Source: MetroPlan Orlando, 2016a)
Figure 3-11 Relationship between CMP Performance Measures and Objectives (Source: MetroPlan Orlando, 2016a)
**ITS Master Plan**

An ITS Master Plan was developed by the MetroPlan Orlando to identify applicable ITS strategies that improves efficiency, safety, reliability of the region’s multimodal transportation system (Gannett Fleming, Inc. et al., 2017). Table 3-25 lists the goals, evaluation criteria, and performance measures used in this ITS master plan. A survey was conducted to prioritize the ITS strategies that are applicable to the MetroPlan Orlando stakeholders. Table 3-26 shows the survey results. It is seen from this table that the ITS strategies with the highest priority are traffic adaptive signals, information management, dynamic routing, and dynamic parking guidance and reservation. An ITS scoring methodology was also developed in the ITS master plan, which takes the following performance measures listed in the 2040 LRTP into consideration.

- Percent of vehicle travel in generally acceptable operating conditions (peak hour)
- Delay for vehicle
- Travel time reliability for vehicle
- Percent miles severely congested (based on Volume to Capacity (v/c) Ratio)
- Combination of truck travel time reliability
- Combination of truck delay
- Combination of truck percent miles severely congested truck
- Percent of congested roadway centerline miles with transit service transit
- On-time performance transit
- Signal retiming cost/benefit
- Incident duration

**Bicycle and Pedestrian Plan**

The MetroPlan Orlando Bicycle and Pedestrian Plan focuses on three areas: 1) providing connectivity and completing missing gaps in the existing bicycle and pedestrian network; 2) serving areas potentially with high demand of bicycle and pedestrian; and 3) identifying improvements that could expand the bicycle/pedestrian network and make the network more user-friendly for commuter trips (MetroPlan Orlando, 2016b). To prioritize bicycle and pedestrian projects, the following measures are used as the scoring criteria:

- Non-motorized trip demand
- Type of accommodation
- Connectivity
- Intermodal
- Local match
- Local plans
- Project readiness

Among these measures, the type of accommodation and connectivity have higher weights.

<thead>
<tr>
<th>Goals</th>
<th>Objectives</th>
<th>Measures</th>
</tr>
</thead>
<tbody>
<tr>
<td>A: Maximize the performance, efficiency, and reliability of the multi-modal transportation system.</td>
<td>A1: Reduce system-wide delay and travel time for automobiles, commercial vehicles, and transit.</td>
<td>Improve travel time and reliability</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Increased trip options/choices by mode for travelers</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Reduction in vehicle hours of delay on the system per person per day</td>
</tr>
<tr>
<td></td>
<td>A2: Reduce delay and travel time on selected corridors for automobiles, commercial vehicles, transit and bicycle / pedestrian facilities using TSM&amp;O.</td>
<td>Identification of priority corridors</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Percentage of corridors managed or monitored</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Improve travel time reliability on corridors during peak hours</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Reduce delay duration during peak hours</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Increased person throughput (point A to point B)</td>
</tr>
<tr>
<td></td>
<td>A3: Reduce vehicle delay from incidents by implementing incident response and special event traffic management programs.</td>
<td>Travel times and speeds</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Reduction in response and clearance times</td>
</tr>
<tr>
<td></td>
<td>A4: Monitor the service life and time in service of ITS devices used in the transportation system in order to reduce costs.</td>
<td>ITS devices are monitored and evaluated on a scheduled basis</td>
</tr>
<tr>
<td></td>
<td>A5: Conduct on-going research regarding future ITS technologies in order to “see” into the future as to what new ITS strategies and equipment are “around the corner”.</td>
<td>Research is routinely conducted on new ITS technologies that takes into account capital equipment, staffing and resource needs</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Pricing information, including variable pricing, is routinely evaluated</td>
</tr>
<tr>
<td>B: Integrate information, communication, and technology to empower systems users to make informed choices.</td>
<td>B1: Improve the reliability and predictability of travel by monitoring the use of the transportation system and the collection of pertinent data.</td>
<td>Conduct traffic counts in real-time for vehicles, transit, bicycles, and pedestrians</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Number and percentage of roadway miles under video surveillance and monitoring</td>
</tr>
<tr>
<td></td>
<td>B2: Provide real-time dynamic travel time and delay information (suggested routes, dynamically-updated) to users.</td>
<td>Identification of locations in need of real-time dynamic travel and delay information</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Reduction in percent of locations and transit routes in need of real-time dynamic traveler information</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Increase in percent of transit routes with real-time monitoring</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Increase in percent of motorists and transit users having access to real-time travel and delay information</td>
</tr>
<tr>
<td></td>
<td>B3: Improve tourist access and mobility through the use of specialized traveler information systems.</td>
<td>Delivery of traveler information by the private sector using information developed by the public sector</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Emergency responders have access to real-time travel and delay information</td>
</tr>
<tr>
<td></td>
<td>B4: Improve service for special traveler needs through the use of ITS applications.</td>
<td>Number and nature of 5-1-1 calls</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Number of www511 visits</td>
</tr>
<tr>
<td></td>
<td>B5: Enhance safe and efficient freight transport and delivery.</td>
<td>Comments to Convention and Visitor Bureau</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Increased access to GPS and other commercial traveler information real-time data sources</td>
</tr>
<tr>
<td></td>
<td>B6: Promote and encourage interagency, interjurisdictional coordination and communications.</td>
<td>Diversity of ITS services for special populations, pedestrians, cyclists, and students is readily available</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Expanded economic opportunity and socioeconomic mobility for underserved populations (i.e., Ladders of Opportunity)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Development of regional interagency operational and communications plans and agreements (ITS regional architecture)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Development of regional set of transportation management plans for planned major events that can be applied to planned events</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Development of list of potential ITS projects each agency could consider when developing their project priorities</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Development of detailed ITS strategies to reduce agency efforts in creating System Engineering (ISE) documents</td>
</tr>

3.2.5.6 Hillsborough MPO

LRTP

The Imagine 2040 LRTP was developed by the Hillsborough MPO, the MPO designated for the Tampa urbanized area (Atkins North America, 2018). A set of six goals and corresponding objectives and policies were specified in the Imagine 2040 LRTP. To achieve these goals, a list of performance measures was determined based on five categories of needs. Table 3-28 summarizes the needs categories and the corresponding performance measures listed in the Imagine 2040 LRTP.

</tbody>
</table>

Notes:
* NA means not available.

It should be pointed out that the types of improvement considered for congestion management of vehicles are as follows.
- Geometric improvement at intersections (for example, adding or extending turn lanes)
- Advanced coordinated signal control and management
- Advanced traffic management system
- Expansion of road ranger patrols and improved incident management
- Freeway operational movement such as variable speed limit, lane control, and ramp metering

**Transportation Improvement Program (TIP)**

The Hillsborough MPO safety measures and targets were stated in its TIP, which are consistent with the national safety measures specified in MAP-21 and the state safety measures (Hillsborough MPO, 2018a). Table 3-29 lists these safety measures and the year 2018 targets for the State as well as the Hillsborough MPO. The safety targets for the Hillsborough MPO listed in this table were derived by using linear projection based on historical 5-year crash data on a rolling average.

</tr>
<tr>
<td>Rate of Fatalities per 100M VMT</td>
<td>0</td>
</tr>
<tr>
<td>Rate of Serious Injuries per 100M VMT</td>
<td>0</td>
</tr>
</tbody>
</table>

In coordination with the Imagine 2040 LRTP, the TIP projects were prioritized by a list of criteria ((Hillsborough MPO, 2018a). The corresponding performance measures are as shown below.
- Preserve the system
  - Bridge repair and replacement
- Road resurfacing
- Transit vehicle replacement
- Reduce crashes and vulnerability
  - Total, fatal and bike/pedestrian crashes per centerline
  - Recovery time and economic impacts from flooding or major storm surge
- Manage congestion for drivers and shippers.
  - Travel time reliability on heavily congested arterials
  - Peak period V/C ratio
- Real choices when not driving
  - Travel time reliability on heavily congested arterials
  - Peak period V/C ratio
- Major infrastructure improvements
  - Density of jobs and population in 2040 within ¼ mile of proposed transit service
  - Density of jobs and population in 2040 within ¼ mile of proposed trail/sidepath

**ITS Master Plan**

An ITS Master Plan was developed by the Hillsborough MPO in 2013 (URS Inc. 2013). This plan focuses on 1) Transportation efficiency and quality; 2) Safety and security, 3) Accessibility and mobility; and 4) Reliable and coordinated operations. As a basis for future plan, the existing transportation and roadway conditions were first examined. The following performance measures were analyzed.

- Average incident duration per lane blocking incident
- Number and type of incidents
- Miles managed by ITS
- Travel time index and buffer index
- Level of service
- Percentage of transit run delays caused by congestion
- Total number of bicycle crashes
- Total number of pedestrian crashes
- Route location and associated multimodal element

A stakeholder survey was conducted to prioritize ITS needs. Based on the survey results, a number of TSM&O and ITS strategies were proposed to meet these needs, as summarized in Table 3-30. Correspondingly, 28 ITS projects were identified.

<td>Improve mobility and reduce vehicle crash rates related to weather and other low visibility events</td>
<td>Develop and deploy a RWIS</td>
<td></td>
</tr>
</tbody>
</table>
| Improve safety and coordination of intermodal conflicts (highway-rail interface/crossings) | Provide crossing gate video enforcement  
Upgrade signal interconnect with traffic signals  
Provide an Active Advanced Warning System (AAWS)  
Evaluate and implement in-vehicle warning systems |
|---|---|
| Identify and develop diversion routes and system strategies | Review regional evacuation plan and disaster response and recovery plan  
Expand and/or enhance the capability to provide regional emergency/traffic text alerts |
| Identify and provide ITS strategies to support regional emergency evacuation plans and response | Provide and/or enhance multi-modal information dissemination and trip planning tools that may affect roadway users and travel choices across all modes  
Provide real-time parking garage/lot space availability with map of Downtown Tampa as part of the 511 mobile app  
Provide commercial truck parking lot space availability as part of the 511 mobile app  
Provide and/or expand real-time travel-time data along arterials |
| Traveler information dissemination | Expand and/or enhance en-route traveler information systems |
| Inter-agency coordination and communications | Develop regional interagency operational and communications plan(s)  
Identify and enhance regional concept of operations, policies, and procedures involving transportation, emergency, and law enforcement stakeholders |

**Freight System Performance Measures for the Tampa Bay Region**

After reviewing the national freight system performance measures as well as the existing freight-related performance measures for the Tampa Bay region, a list of potential freight performance measures were recommended by for the Tampa Bay region (FDOT District 7, 2014), as shown in Table 3-31. This table also shows the assessment of these performance measures in terms of understandability, usefulness, potential for forecasting, ease of data collection, and data quality.

**Roadway Level of Service Report**

A 2015 level of service report for the city of Tampa and a 2017 roadway level of service report for the Hillsborough COUNTY were produced by the Hillsborough MPO to reflect the current level of service of county roadways and state roadways within the area (Hillsborough MPO, 2017; Hillsborough MPO, 2018b). Below is a list of information contained in these report for each roadway section.

- Section description
- Jurisdiction
- Strategic intermodal system
- Number of lanes per direction
- Length
- Current posted speed of the segment
- Standard level of service (that is, the level of service that shall be maintained)
- Local functional class
- Average annual daily traffic
- Peak hour peak direction volume that is calculated as the 100th highest hour traffic volume
- Maximum service volume (that is, daily capacity)
- Peak hour peak direction maximum service volume
- Volume to capacity ratio
- Current level of service as determined by using FDOT generalized LOS table

**State of the System Report**

A 2016 State of the System Report was produced by Kimley-Horn and Associates, Inc. (2016) for the Hillsborough MPO to demonstrate how transportation system addresses community needs and satisfies the goals specified in the long range transportation plan. In this report, a number of performance measures were calculated and they are summarized in Table 3-32.
<table>
<thead>
<tr>
<th>Focus Area</th>
<th>Goal</th>
<th>Performance Measure</th>
</tr>
</thead>
</table>
| System preservation        | Maintain roadway pavement                 | • Safety – wheelpath, rutting, friction  
• Preservation – cracking, potholes, raveling, patching, depressions  
• Ride – rippling, faulting, public complaints  
• Standardized Pavement Condition Index (PCI) |
| Maintain and replace bridges |                                           | • Total bridge counts and percentage of bridges in either good or poor condition |
| Preserve the transit fleet |                                           | • Average age of fleet                                                             |
| Minimize traffic           | Reliable travel time for drivers and shippers | • Peak hour travel reliability  
• Peak hour truck travel reliability  
• Travel speed, delay, and travel time index during AM and PM peak hour |
| Safety and security        | Reduce crashes                             | • Total number of crashes  
• Total number of fatalities  
• Total number of injuries  
• Number of auto, pedestrian, bicyclist, and motorcycle fatal crashes  
• Injury crashes per 100 million VMT  
• Fatality crashes per 100 million VMT |
| Improve resiliency         |                                           | • Annual stormwater and flooding investment  
• Weeks of disruption  
• Economic losses of a typical category 3 storm |
| Real choices               | People and jobs served by the bus system  | • Passengers per revenue hour  
• On-time performance (at time periods from -1 to 5+ minutes)  
• Countywide population and jobs within ¼ mile of frequent and somewhat frequent transit service  
• Transportation disadvantaged living outside of bus service area |
|                            | People served by the trail network        | • The miles of trails  
• The percentage of residents with access to trail |
| Major investments          | Jobs served                               | • Number of jobs  
• Percentage of roads having traffic volume that is greater than capacity |
3.2.5.7 North Florida TPO

LRTP

The 2040 LRTP of the North Florida TPO consists of six goals that aim at enhancing economic competitiveness, livability, safety, mobility and accessibility, equity in decision making, and system preservation. Accordingly, a number of objectives and performance measures were proposed. Tables 3-33 to 3-37 list those objectives, performance measures, and benchmarks included in the North Florida MPO LRTP.

</table>

Table notes:

(1) This performance measure will not change significantly from year to year unless major route changes or new transit operations are deployed.
(2) Coordination with Jacksonville Transportation Authority is needed to develop the baseline and benchmark data needed.
(3) Many exogenous factors influence this performance measure including the price of fuels that are beyond the scope of a LRTP. However, this performance measure will be considered within the LRTP based on policy decisions made during the scenario development.
(4) Emissions will be determined using Florida emission factors from the FHWA Moves model.
(5) Based on modeling provide by the Northeast Florida Regional Council.

</tbody>
</table>

(1) These measures may not apply on corridors not selected for context-based solutions that may intentionally lower the running speed or capacity.

(2) Generally, increases in the quantity traveled (throughout) are preferred. However, consistent with livability and sustainability goals, one objective is to reduce the amount of travel needed. Therefore, no benchmarks are proposed, but monitoring is recommended.

(3) These performance measures will not change significantly from year to year but will be evaluated in each major update to the LRTP to establish benchmark and monitor performance.

</table>
As measures of effectiveness, the Northeast Regional Planning Model, NERPM-AB, together with other tools were used to quantify the performance measures for the Cost Feasible Plan compared to the base no-build scenario. Table 3-38 shows the measures and how these measures satisfy the benchmark requirement set by the LRTP.

**Strategic Safety Plan**

A strategic safety plan was developed by the HNTB Corp. for the North Florida TPO (HNTB Corp., 2015a). It set up three safety-related goals, that is,

- 5% reduction in fatality and injury crashes
- 5% reduction in crash rate
- Advance safety funding for projects located on corridors and intersections with high priority.

These three goals were addressed by a number of strategies, which are quantified by the following performance measures.

- Crash rate
- Number of first responders who have participated in Time4Safety training or National Traffic Incident Management Training
- Teen and distracted crash rate
- Vulnerable roadway users’ fatal crash rate
- Red light running crash rate
- Impaired driving crash rate
- Fatal crash rate
- Lane departure crash rate
- Intersection crash rate

</table>
**Congestion Management Process (CMP)**

The congestion management process of the North Florida TPO follows the eight elements of FHWA CMP elements (HNTB Corp., 2015b). As shown in Figure 3-12, the development of multimodal performance measures is the third step of this process after developing regional objectives and CMP network. The performance measures used in the CMP are the same as those listed in Tables 3-33 to 3-37.

![Figure 3-12 FHWA Congestion Management Process Element](image)

To address the congestion problem, a list of strategies proposed in the CMP plan, which are as follows.

- TSM&O strategies
  - Surveillance and incident management systems
  - Access management
  - Congestion pricing
  - Integrated corridor management
  - Arterial management systems
  - Hard shoulder running
  - Reversible lanes
  - One-way streets
  - Ramp metering
  - Transit signal priority
  - Variable speed limits
o Dynamic detours
o Queue warning systems
o Traveler information systems

• Traveler demand management strategies
  o High-Occupancy Vehicle (HOV) incentives
  o Park-and-ride lots
  o Multimodal transportation centers
  o Commuter assistance service programs

• Transit improvements
  o Local bus service improvements
  o Express bus service improvements
  o Bus rapid transit improvements
  o Light rail transit improvements
  o Commuter rail improvements

• Capacity improvements
• Add new lanes
• Add new managed lanes
• Intersection improvements
• Interchange improvements
• Add auxiliary lanes

It should be noted that high priority was given to TSM&O strategies and traveler demand management strategies, and less priority was assigned to capacity improvement projects.

**Annual Mobility Report**

An annual mobility report was produced by the North Florida TPO for year 2014 (HNTB, 2014). The mobility performance measures listed in Table 3-36 were reported on a five-year basis from 2008 to 2012 in this document. The data source is the FDOT Mobility Performance Measures database for the year 2012. The data are from the statewide telemetered traffic monitoring system (TTMS).

**North Florida Regional ITS Master Plan**

The North Florida MPO developed a regional ITS master plan in 2010. In this plan, the existing ITS deployments and programmed ITS projects within the region were summarized. Priority corridors for ITS deployment were identified by stakeholders through a project kickoff meeting. The ITS needs and cost estimates were then developed for the existing and programmed ITS projects along the prioritized corridors. Since this ITS master plan was developed in 2010, performance measures were not considered in this plan.
3.3 Performance Measure Estimation Methods and Tools

3.3.1 Safety

3.3.1.1 Roadway Safety Data Dashboards

The office of Safety’s Roadway Safety Data Dashboards under the FHWA provides a web-based application that can create safety data dashboards at national, state, regional, and MPO levels (FHWA, 2018b). It is based on the data from NHSTA’s FARS database and the data has a range up to year 2015. The state and national VMT are obtained from the FHWA’s Highway Statistics Series, and MPO boundaries are derived from the FHWA’s HEPGIS tool. The tool allows users to select fatality type, collision type, collision location, and types of person involved in the fatal crashes. Figure 3-13 shows an example of roadway safety data dashboard produced by this tool for Miami-Dade County at the MPO level.

![Figure 3-13 Example of FHWA Roadway Safety Data Dashboard](image)

3.3.1.2 Florida ITS Evaluation Tool

The Florida ITS Evaluation (FITSEVAL) is a sketch-planning tool that evaluates the benefits of ITS in the FSUTMS/Cube Environment (Hadi et al., 2008). The tool uses a predictive method to estimate crash rates similar to the one used in the ITS Deployment Analysis System (IDAS) Tool. Table 3-39 shows the crash rates of property damage only (PDO), injury and fatality for freeway and arterial segments used in FITSEVAL as a function of Volume to Capacity (V/C) ratio. The total number of crashes is then estimated by multiplying the crash rate with Million Vehicle Miles Traveled (MVMT). The safety impacts of ITS strategies are studied by applying a corresponding crash modification factors.

#### 3.3.1.3 Florida Specific Safety Performance Function

Safety measures for past years can be directly calculated from historical crash data. However, for the future years, as data is not available, safety measures have to be estimated either from a crash rate look up table as describe in the previous section or from a safety performance function (SPF). SPF is defined in the Highway Safety Manual (HSM) as a regression model that can be applied to predict the average number of crashes on a roadway segment or at an intersection. Alluri et al. (2016) developed calibrated SPFs specifically for Florida based on roadway inventory data and crash data. Equation 3-10 presents the general form of an SPF function for a roadway segment and ramps.

\[
N_{predicted} = e^{a \times AADT^b} \tag{3-10}
\]

where \(N_{predicted}\) is the number of predicted crashes per mile per year and AADT represents average annual daily traffic. \(a\) and \(b\) are regression coefficients.

Equation 3-11 presents the SPF functional form for an intersection.

\[
N_{predicted} = e^{a \times AADT_{major}^b \times AADT_{minor}^c} \tag{3-11}
\]

where \(AADT_{major}\) and \(AADT_{minor}\) represent the average annual daily traffic for the major and minor approaches of an intersection, respectively. Symbols \(a\), \(b\), and \(c\) are regression coefficients.

Alluri et al. (2016) also calibrated the default SPFs used in Safety Analyst, an advanced safety analysis tool, by application a calibration factor \(C\) for Florida. Tables 3-40 to 3-43 summarize the results of this calibration for arterial streets, freeways, intersections, and ramps, respectively.

3.3.1.4 Safety Performance Functions and Crash Modification Factors Used in the SHRP2 C11 Post-Processor Tool

The SHRP2 C11 post-processor tool was developed by Cambridge Systematics, Inc. (2016) to produce travel time reliability measures and safety measures for future years. This tool was produced as part of an effort funded by a grant awarded to FDOT for the reliability data and analysis tools proof of concept pilot study under the fourth round of the SHRP2 implementation assistance program in November 2014. The SPF functions used in this tool was originally developed by the University of Central Florida (UCF). Table 3-44 presents the SPFs for highway segments, while the equations in Table 3-45 lists the SPFs for intersections. The SHRP2 C11 tool uses crash modifications factors to consider the impacts of safety improvements. Table 3-46 shows the values of the crash modification factors used in this tool. These factors were determined based on FHWA references and other literature.

3.3.2 Travel Time

3.3.2.1 Traffic Flow Models

A number of traffic flow models (TFMs) have been used in the planning studies to estimate travel time based on demand and capacity. Below is a description of the most commonly used TFMs.

*Bureau of Public Roads (BPR) Curve*

The BPR curve has been widely used in travel demand models to calculate link travel time. Equation 3-12 shows the expression of the BPR curve.

\[
t_i = t_0 \left[ 1 + \alpha \left( \frac{v}{c} \right)^\beta \right]
\]  

(3-12)

where \(t_i\) is congested travel time and \(t_0\) is free-flow travel time for link \(i\). \(v\) refers to traffic volume on link \(i\) and \(c\) is link capacity. \(\alpha\) and \(\beta\) are the BPR coefficient and the BPR exponential coefficient, respectively, whose values vary with the function class of links and are usually calibrated for local conditions.

*Akcelik Equation*

The expression for Akcelik equation is shown in Equation 3-13.
\[
t_i = t_0 \left[ \frac{1}{v_0} + (g_{pb} \times g_T \times (\frac{v}{c} + g_{AkcelikOffset} - 1) + \right. \\
\left. \sqrt{\left(\frac{v}{c} + g_{AkcelikOffset} - 1\right)^2 + (g_{pa} \times g_P \times \left(\frac{v}{c} + g_{AkcelikOffset} \times c \times g_T\right))} \right] / \left(\frac{1}{v_0}\right)
\]

(3-13)

where \(v_0\) is free-flow speed in mph. \(g_{pb}\) and \(g_{pa}\) are facility specific parameters. \(g_T\) is the length of the time period in hours. \(g_{AkcelikOffset}\) is an Akcelik offset parameter, which contributes to the shape of the volume delay curve by shifting the base of the curve from a travel time ratio of 1.0. Akcelik equation has been used in the Express Lanes Time of Day (ELToD) model, a tool developed by the Florida Turnpike Enterprise (2012) to evaluate a tolled corridor at a sketch planning level.

**Modified Greenshields Model**

Modified Greenshields model has been applied in a number of Dynamic Traffic Assignment (DTA) simulation tools including DynaSmart and DynusT. A single-regime modified Greenshields model is used for arterials, which is express as follows.

\[
s - s_0 = (v_f - s_0)(1 - \frac{k}{k_j})^\alpha
\]

(3-14)

where \(s\) is the speed. \(k\) symbolized the density and \(k_j\) is the jam density. \(s_0\) represents the minimum speed, \(v_f\) denotes the speed-intercept, and \(\alpha\) is a coefficient in this model. For freeways, a dual-regime modified Greenshields model is used in DTA tools. The expression for the dual-regime modified Greenshields model is listed below:

\[
s = s_f \quad 0 \leq k \leq k_{bp}
\]

\[
s - s_0 = (v_f - s_0)(1 - \frac{k}{k_j})^\alpha \quad k > k_{bp}
\]

(3-15)

where \(k_{bp}\) is the density at the breakpoint for two modeling regimes, and \(s_f\) is the free-flow speed. The other variables are as defined above. The speed given by the modified Greenshields model can be converted into travel time by using the segment length divided by the calculated speed.

**A Piecewise Modified Davison Volume-Delay Function**

A piecewise modified Davison volume-delay function has been developed by Moses et al. (2013) in a study of SR 9/I-95 in Pompano Beach, Florida. This function was further used in the SHRP2 C11 post-processor tools (Cambridge Systematics, 2016). Equation 3-16 shows this volume-delay function.
where \( s \) is speed and \( s_0 \) is free-flow speed. \( J_D \) is a delay parameter. \( \mu \) is saturation threshold parameter.

### 3.3.2.2 Highway Capacity Manual Computational Engine

Procedures have been included in the Highway Capacity Manual (HCM) to calculate the time-dependent traffic conditions along freeway facilities and arterial streets. The corresponding computational engines are called FREEVAL (for freeways) and STREETVAL (for urban streets), respectively, in addition to the commercially available Highway Capacity software (HCS). In freeway facility analysis, a freeway facility is divided into four types of segments, including basic, merge, diverge, and weaving segments. When traffic is under congestion, segments are analyzed independently. Depending on segment type, the corresponding HCM procedure is applied to calculate segment speed. When traffic is oversaturated, freeway facility is analyzed as a node-link system and a cell transmission model is utilized to track queue formulation and dissipation over multiple time periods and segments. The output performance measures include travel time, speed, delay, queue length, VMT, VHT, and LOS for each individual segment.

In urban streets analysis, urban street facilities are coded as segments with boundary nodes that represent signalized or unsignalized intersections. The automobile mode performance of segments is determined by first analyzing the segment running time and through movement delay based on control type and segment free-flow speed, and then calculating the segment travel speed, stop rate, and level of service. The level of service of a signalized intersection is determined by control delay, which is a function of adjusted saturation flow and percentage of vehicles arriving on green. The travel time along a segment can be derived from segment travel speed.

### 3.3.2.3 Macro-, Meso-, and Microsimulation Models

Macro-, meso-, and micro-level simulation models can be applied to obtain travel time along a segment or a route. However, these models vary in terms of the details of network and driving behaviors. Macroscopic models (for example, regional travel demand models) consider vehicles as a whole and utilize traffic flow model to determine the traffic condition on a link or section. Microscopic simulation provides a detailed modeling of road network. Individual vehicle movements are governed by car-following, lane changing, and gap acceptance behaviors. However, microscopic modeling requires significantly more efforts to calibrate. Examples of microscopic models are VISSIM, CORSIM, PARAMICS, AIMSUN, and TransModeler. Mesoscopic simulation models are in between macroscopic and microscopic simulations. In mesoscopic model, vehicles are modelled either individually or as packets of a small number of vehicles. However, the movements of vehicles or packets of vehicles are determined by the
macroscopic traffic flow models. The queuing and queue spillback are usually captured by considering the constraints of capacity and link storage. Compared to microscopic simulation, mesoscopic simulation requires less effort to calibrate and has a faster running time. Examples of mesoscopic simulations are Dynasmart, DynusT, Direct, Cube Avenue, AIMSUN, VISSIM meso, and Dynameq.

3.3.3 Travel Time Reliability

3.3.3.1 SHRP 2 L02 Method

The SHRP2 L02 project provides a data-based travel time reliability estimation method (Institute for Transportation Research and Education et al., 2012). This method consists of three modules, that is, a data manager, a computational engine, and a report generator. The data manager assembles data from traffic sensors, weather data feeds, and incident reporting systems, and organizes them in a database. The computational engine classifies traffic into different regimes based on demand, incident, and weather. The probability density function (PDF) and cumulative density function (CDF) distributions of travel time rate for each regime are calculated from the collected and cleaned data. These two distributions allow the visualization and comparison of travel time reliability under various traffic conditions as well as the identification of contributing factors to unreliability. The report generator presents results based on user requests.

3.3.3.2 Highway Capacity Manual Computational Engine

FREEVAL-RL, STREETVAL-RL, and HCS reliability procedures apply modeling methods developed to estimate travel time reliability for freeway facilities and urban street facilities, as part of the SHRP 2 Reliability L08 project. These tools have a scenario generator, which takes the input of demand, weather, incident, and work zone data, and generates a set of scenarios that represent different traffic conditions that are expected to occur within one year along the study facility. The impacts of incident, weather, and work zone events on capacity and speed are adjusted by using adjustment factors recommended by HCM. The conventional HCM computational engine for freeway or urban street facility is then utilized to calculate the travel time for each scenario. The measures of travel time reliability, including standard statistical measures (e.g., standard deviation, kurtosis), percentile-based measures (e.g., 80th and 95th percentile travel time, buffer index), on-time measures (e.g., percent of trips completed within a travel time threshold), and failure measures (e.g., percent of trips that exceed a travel time threshold), are calculated from the resulted distribution of travel time.

3.3.3.3 SHRP2 L07 Method

The SHRP2 L07 project developed a sketch planning-level tool for assessing the impacts of highway design treatments on travel time reliability (Potts et al., 2014). The method used in the L07 project was originally developed in the SHRP2 L03 project and updated in the L07 project to account for the effects of snow and ice. Equation 3-17 presents the general functional form developed in the SHRP2 L03.

\[
TTI_{n\%} = e^{(j_{n} LHL + k_{n} d_{crit} + l_{n} R_{0.05})}
\] (3-17)
where TTI_n% is nth percentile travel time index. Depending on the coefficients used in Equation 4-8, different percentile of travel time index can be estimated. LHL is the lane hour lost due to incidents and work zone. This value is calculated as the average number of lanes blocked per incident or work zone multiplied by the average duration of incident or work zone and the total number of incidents/work zones within the study time period and study time slice. $d_{crit}$ represents the critical demand-to-capacity ratio. Two methods were recommended to calculate demand. In the first method, when there is no congestion, the 30th-highest volume count during one-year weekdays is used as the demand. However, as traffic detectors measure volume counts instead of demand during the congested periods, a demand has to be either estimated by using a cumulative volume-based method proposed by the L03 project or by adding a field-observed number of vehicles in queue for congested periods. When there is only a single-day or multiple-day collection of volume counts, these limited volume counts are converted to the counts in the peak month using a seasonal factor and a weekday adjustment factor.

The parameter $R_{0.05^*}$ in Equation 3-17 is the hours of rainfall with a precipitation greater than 0.05 inch during the time slice and study period. The remaining variables in Equation 3-17 are regression coefficients, whose values are listed in Table 3-47.

A study by Jia et al. (2014) found that the TTI produced by the above equations are more sensitive to the number of incidents and incident duration than other factors such as demand and weather. The predicted TTI value using Equation 3-17 also has a large difference from that calculated based on real-world data. Therefore, a similar regression procedure was utilized by Jia et al. (2014) to derive expressions for travel time indices based on data for I-95 in Miami, FL. Equation 3-18 shows the final expressions and the parameters in this equation are listed in Table 3-48.

$$TTI_{n%} = e^{b_1*d_{crit}+b_2*LHL+b_3*Rain+b_4*Length+b_5} + b_6$$ (3-18)

3.3.3.4 SHRP2 C11 Method

The SHRP2 C11 post-processor was developed to provide the capability to estimate the impacts of different strategies on travel time reliability and crashes (Cambridge Systematics, Inc., 2016), as mentioned earlier. In this post-processor, travel time reliability measures are calculated as a function of the mean travel time index, as shown below.

For freeways,

\[
T_{TI50} = \begin{cases} 
10.4910 - 9.5867 \times e^{-0.0142 \times X^{2.2367}} & \text{for } X > 1.07 \\
0.963X + 0.037 & \text{otherwise}
\end{cases} 
\]

\[
T_{TI80} = \begin{cases} 
7.3567 - 6.9965 \times e^{-0.0910 \times X^{2.0185}} & \text{for } X > 1.03 \\
1.0 & \text{otherwise}
\end{cases} 
\]

\[
T_{TI95} = \begin{cases} 
11.7933 - 16.2178 \times e^{-0.3855 \times X^{1.0336}} & \text{for } X > 1.08 \\
1.3737X - 0.3737 & \text{otherwise}
\end{cases} 
\]

where X is mean travel time index. T_{TI50}, T_{TI80}, and T_{TI95} are the 50\textsuperscript{th}, 80\textsuperscript{th}, and 95\textsuperscript{th} travel time index, respectively.

For arterials,

\[
T_{TI50} = \begin{cases} 
0.9333 \times (101.7049 + 12.887 \times X^{2.403}) & \text{for } X < 1.07 \\
101.7049 + X^{2.403} & \text{otherwise}
\end{cases} 
\]

\[
T_{TI80} = \frac{0.7266 \times 26.26 + 9.6702 \times X^{2.5698}}{26.26 + X^{2.4398}} 
\]

\[
T_{TI95} = 21.1669 \times e^{-2.9506 \times X} 
\]

Equations 3-19 to 3-24 were obtained by using regression analysis for the freeways and arterials in a number of counties in Florida based on the National Performance Management Research Data Set (NPMRDS) for years 2014 and 2015.

The expression for the calculation of the mean travel time index is given in Equation 3-25.

\[
X = 1 + (FFS \times (RecurringDelayRate + Du)) 
\]

where FFS is free-flow speed. RecurringDelayRate is the recurring delay rate in hours per vehicle-mile, which is estimated as follows.

\[
RecurringDelayRate = (1/\text{Speed}) - (1/\text{FFS}) 
\]

where Speed is the calculated link or segment speed based on the piecewise modified Davison equation.
Du is base nonrecurrent delay rate due to incidents. The following regression equations are applied to calculate Du.

\[
Du = -\frac{0.0111}{1 - 1471 \times \exp(-6.8498 \times \frac{v}{c})} \text{ when number of lanes} \leq 2
\]

\[
Du = -\frac{0.0085}{1 - 1872 \times \exp(-7.1381 \times \frac{v}{c})} \text{ when number of lanes} = 3
\]

\[
Du = -\frac{0.0068}{1 - 1827 \times \exp(-7.1090 \times \frac{v}{c})} \text{ when number of lanes} \geq 4
\]

The implementation of an incident management strategy may reduce incident rate or duration, which results in a lower incident delay. The new incident delay rate Da is calculated as follows.

\[
Da = Du \times (1 - R_f) \times (1 - R_d)
\]

where R_f and R_d are the reductions in incident frequency and incident duration in fractions, respectively.

### 3.3.4 Energy Consumption and Emissions

#### 3.3.4.1 MOVES

The Motor Vehicle Emission Simulator (MOVES) is an emission estimation tool released by the Environmental Protection Agency (EPA). The MOVES model can estimate emissions at three different scales: national, county, and project levels (U.S. Environmental Protection Agency, 2015). The national and county scales are usually used for a large or medium area while the project scale analysis is targeted for small to medium network. The project level is the finest level of vehicle emission estimation in MOVES. It includes three different estimation methods: the average speed approach, the drive schedule approach, and the operating mode distribution approach. The average speed approach is the simplest methods of the three approaches. It estimates emissions based on average speed and vehicle mile travelled by vehicle type. This approach can be integrated with various levels of modelling tools to estimate emission by using the link-based performance measures exported from these models as input. The drive schedule method estimates emissions based on second-by-second speed profiles of vehicles. However, this method only allows the input of one representative speed profile from traffic models. The operating mode distribution approach is a detailed emission estimation approach that requires the input of the distribution of each operating mode. Operating modes are defined based on Vehicle-Specific Power (VSP), vehicle speed, and vehicle acceleration. These information can be generated from mesoscopic or microscopic simulation outputs.

#### 3.3.4.2 MOVES Lite

As MOVES is a computational intensive emission estimation model requiring a large number of data input, Liu and Frey (2013) developed a simplified and light version of MOVES called MOVES Lite. In MOVES Lite, input parameters, such as temperature, humidity, air conditioning
load, fuel properties, and so on, are considered to be constant as modeling and simulation scenarios usually represent a short period of time on a typical day. Such an assumption greatly reduces the computation effort required by the full version of MOVES and leads to a simplified estimation of cycle average emission rates for different operating modes. MOVES Lite has been implemented in the dynamic traffic assignment tool, DTALite. Figure 3-14 illustrates the vehicle emission rates used in DTALite.

![Vehicle Emission Rates Used in DTALite](image)

**Figure 3-14 Snapshot of Vehicle Emission Rates Used in DTALite**

### 3.4 Summary

This section provides a summary of performance measures that have been reviewed in this document. Tables 3-49 to 3-55 summarize these performance measures based on the categories of mobility, reliability, safety and security, fuel consumption and environment, system preservation, freight, and livability and sustainability, which correspond to the seven focus areas of MAP-21. Note that a large number of performance measures listed in these tables are reported by the State and MPOs, however, no detailed calculation methods or data sources are explained. When available, the methods used in the calculation of the measures are reported.
### Table 3-49 Summary of Mobility Performance Measures

### 3.5 Conclusions and Recommendations

Based on the literature review presented in this chapter, it can be concluded that there are a large number of metrics that have been identified and utilized at the national level, by FDOT departments, and by various MPO/TPO/TPA in Florida, as listed in Table 3-49 to 3-55. Some of these measures will be calculated in the initial version of the updated FITSEVAL. Others, will be calculated in future versions as needed. Specifically, the following can be concluded:

- A wide range of performance measures have been selected, calculated, and reported by different FDOT departments for different purposes. These measures will be considered to be calculated by the developed tool. Examples of the measures are those identified in the FDOT Florida Transportation Plan (FTP), FDOT TSM&O Strategic Plan, and FDOT Multimodal Mobility Performance Measure Source Book.

- Metropolitan planning organization/transportation planning organization/transportation planning agency (MPO/TPO/TPA) in Florida have included performance management into their planning process. The performance measures used by MPOs/TPOs/TPAs vary with their specific goals and objectives. The safety performance measures are more consistent among MPO/TPO/PTAs, while there is a large variation in other performance measures. There is no standard regarding what performance measures should be reported. A number of MPOs/TPOs/TPAs have set up targets according to the required national performance measures.

- The final rule of the Moving Ahead for Progress in the 21st Century Act (MAP-21) MAP-21 have clearly specified the national performance measures in seven focus areas that need to be calculated by state and MPOs. The calculation method, data source, and reporting date for those performance measures are also provided in detail.

- As MPOs/TPOs/TPAs place more emphasis on multimodal transportation system, it is recommended not only to calculate automobile-related performance measures, but also multimodal performance measures that are related to transit, trucks, pedestrians, and bicycles. The developed tool should be updated to allow the calculation of multimodal performance measures based on modeling, where possible.

- A number of methods have been identified to calculate safety, mobility, reliability, and emission performance measures. These methods can be either data-based or model-based.
4. PERFORMANCE MEASURE ESTIMATION FOR BASE CONDITION

Different methods are reviewed in this study for potential use in FITSEVAL to estimate the mobility, reliability, and safety performance for the base conditions before implementing advanced technologies. The estimation can be based on real-world data, utilizing different analytical models or simulation. Methods to estimate travel time and travel time reliability are assessed in this study by comparing the resulting estimates from applying these methods to those estimated based on real-world data.

4.1 Mobility Performance Measure Estimation

Mobility is the most important widely used performance measurement category considered in planning studies. Examples of mobility performance measures include annual hours of peak hour excessive delay (PHED) per capita and the percent of non-SOV travel as specified by MAP-21 (FHWA, 2017), vehicle mile traveled (VMT), vehicle hour traveled (VHT), average speed, average travel time, throughput, level of service, and so on. Many of the mobility measures can be derived based on travel time and volume estimates. A complete set of mobility performance measures was presented in Chapter 2. This section provides a detailed review of how mobility measures can be forecasted for future years.

4.1.1 Estimation of Mobility Performance Measures based on Data

This section presents a review the definition of the measures and methods of commonly used to estimate the mobility measures for the existing conditions based on data before moving onto the forecasting of these measures. Table 4-1 presents this review.

### 4.1.2 Forecasting Mobility Performance Measures

This section provides a detailed review of methods that have been used for forecasting travel time in the literature.
4.1.2.1 Traffic Flow Models

As shown in Table 4-1, all the mobility performance measures listed in this table are derived from the travel time or speed values, which are usually obtained based on a traffic flow model (TFM) in travel demand models. A number of TFMs have been used in the planning studies to estimate travel time based on demand and capacity. Below is a description of the most commonly used TFMs.

**Bureau of Public Roads (BPR) Curve**

As part of the 1965 Highway Capacity Manual (HCM), the Bureau of Public Roads (BPR) developed a relationship between speed and flow commonly referred to as the BPR curve. This relationship has been widely used in travel demand models, including those in Florida, as a link capacity-based Volume-Delay Function (VDF). The curve suggests that if volume (or flow) increases relative to the capacity, the speed would decrease (or the travel time would increase). By definition, the BPR curve defines delay as a function of link length instead of the number of vehicles in the queue (NCHRP, 1999). Thus, the shorter is the coded link with the high volume/capacity (V/C) ratio, the lower is the delay. No spillback of congestion is projected to upstream links. In addition, the model allows inputting v/c ratios higher than 1.0. These are major deficiencies in the BPR curve and similar VDF relationships.

In Florida, the BPR curve is widely used in the FSUTMS (Florida Standard Urban Transportation Model Structure) models to produce the congested time (or speed) in a capacity restraint route choice assignment. Although the BPR curves are very popular in static route choice assignment as part of demand forecasting, it is often criticized for underperforming in congested traffic conditions where demand exceeds capacity. For instances, the Treasure Coast Regional Planning Model (TCRPM) used BPR curve to determine average travel speed (FDOT, 2014). Researchers and practitioners often raised questioned on this kind of application as there are no situations where V/C is higher than 1.0 in the real world. Queue forms in the real world when demand exceeds capacity, while the passing volume on the congested link does not exceed the queue discharge rate, which is lower than capacity.

Equation 4-1 shows the expression of the standard BPR curve.

\[
t_i = t_0 \left[ 1 + \alpha \left( \frac{v}{c} \right)^\beta \right]
\]

where \( t_i \) is congested travel time and \( t_0 \) is free-flow travel time for link \( i \). \( v \) refers to traffic volume on link \( i \) and \( c \) is practical capacity. \( \alpha \) and \( \beta \) are the BPR coefficient and the BPR exponential coefficient, respectively, whose values vary with the function class of links and are usually calibrated for local conditions. The traditional value for \( \alpha \) and \( \beta \) are 0.15 and 4 (Martin, 1998). However, the value of \( \alpha \) could vary from 0.1 to 1.0 and value of \( \beta \) could vary from 4 to 11 (Dowling, 1997). Different studies have calibrated BPR equation for various conditions and found different sets of values for the parameters (Dowling, 1997; Martin, 1998; Moses et al., 2013; and Horowitz et al. 2014). Also it should be noted that, the practical capacity in equation (2-1) that is used in the demand model is often defined as 80% of the link capacity and the free-flow travel time is often assumed to equal 1.15 times the speed at the practical capacity.
(Dowling, 1997). In this study the base $\alpha$ and $\beta$ parameter values were obtained from a well-calibrated regional model in Florida (e.g. the South East Regional Planning Model (SERPM)).

**Modified Davison Function**

Davison (1966) developed a flow-travel time relationship based on the queuing theory concept. It was a widely accepted model in the late 1970s and the 1980s. The main drawback of the Davison model was that it does not work for oversaturated condition. Therefore, Akcelik (1978) has proposed a Modified Davidson Function, as shown in Equation 4-2.

$$
S = \begin{cases} 
\frac{S_0}{1 + J_D(\frac{V}{C}) / (1 - \mu)} & \text{for } \frac{V}{C} \leq \mu \\
\frac{S_0}{1 + J_D \times \mu + J_D(\frac{V}{C} - \mu)} & \text{for } \frac{V}{C} > \mu 
\end{cases} (4-2)
$$

where $s$ is speed and $s_0$ is free-flow speed. $J_D$ is a delay parameter and $\mu$ is saturation threshold parameter. Note that, these parameters are location specific. Proper calibration need to be performed before using it for a local condition. The Modified Davidson function was also further used in the SHRP2 C11 post-processor tools (Cambridge Systematics, 2016).

**Akcelik’s Equation**

Akcelik (1991,1996) further modified Davidson’s function as mentioned earlier and proposed a new equation is shown in Equation 4-3.

$$
t = t_0 \left\{ 1 + 0.25 \frac{T}{t_0} \left[ (x - 1) + \sqrt{(x - 1)^2 + \frac{8J_A}{cT}} \right] \right\} (4-3)
$$

where, $t$ and $t_0$ are the average and free-flow travel time per unit distance, $T$ is the flow period (typically 1 hour), $x$ is the degree of saturation ($v/c$ ratio), $c$ is the capacity and $J_A$ is the delay parameter.

Akcelik equation has been adopted by Florida Turnpike Enterprise (2012) as the traffic flow model used in the Express Lanes Time of Day (ELToD) model. ELToD is used to evaluate a tolled corridor at a sketch planning level. It is also used to estimate travel time for freeway oversaturated conditions in the FDOT Multimodal Mobility Measures Source Book (FDOT, 2017b). The modified form of Akcelik equation that has been used in ELToD is show in Equation (4-4)

$$
t_i = t_0 \left[ \frac{1}{v_0} + (g_{pb} \times g_T \times \left( \frac{v}{c} + g_{AkcelikOffset} - 1 \right) + \sqrt{(\frac{v}{c} + g_{AkcelikOffset} - 1)^2 + (8 \times g_p \times \left( \frac{\frac{v}{c} + g_{AkcelikOffset}}{c \times g_T} \right))} ) / (\frac{1}{v_0}) \right] (4-4)
$$
where $v_0$ is free-flow speed in mph, $g_T$ is the Akcelik T, $g_{pb}$ is the constant multiplied by the Akcelik T value to calibrate the curve to observed traffic condition, $g_P$ is the facility specific parameter, $v/c$ is the volume to capacity ratio, and $g_{AkcelikOffset}$ contributes to the shape of the volume delay curve by shifting the base of the curve from a travel time ratio of 1.

**Conical Delay Function**

The Conical Delay function was developed by Spiess (1990) focusing on overcoming the inherent drawbacks of the BPR function. A typical form of Conical delay function is shown in Equation 4-5.

$$t = t_0 \left( 2 + \sqrt{b^2 \cdot (1 - x)^2 + a^2 - b \cdot (1 - x) - a} \right)$$

Where $t$ is the travel time, $t_0$ is the free flow travel time, $a$ is a calibration parameter ($< 1$), $x$ is the v/c ratio, and $a = (2b - 1)/(2b - 2)$. The Conical Delay function is computationally efficient and overcome the limitation of BPR curve (Dowling, 1997).

### 4.1.2.2 Calibrated Models for Florida

As part of a FDOT research project conducted by Florida State University (FSU) (Moses et al., 2013), different volume delay function has been calibrated in order to better utilize the travel forecasting models. Four different volume delay functions (VDFs), namely the Modified BPR, Modified Davidson, Akcelik, and Conical functions were calibrated for three different area types (rural, urban, and residential) of two different facilities (uninterrupted and interrupted flow facilities). For the uninterrupted facility type (freeways), the study selected a location on SR-9/I-95 in Pompano Beach, FL. However, for the interrupted facility type, the study estimated the parameters based on simulated data, as none of the permanent detector data could provide the full range of v/c values. The model results show that for the freeways, the Modified BPR function fits the data the best, followed by the Modified Davidson, conical and Akcelik functions. For arterial, the Akcelik function and the BPR function fitted the data the best, followed by the modified Davidson and the conical functions. The calibrated models of FSU are presented in Table 4-2.

### 4.1.2.3 Highway Capacity Manual Procedures

Procedures have been included in the Highway Capacity Manual (HCM) to calculate the time-dependent traffic conditions along freeway facilities and arterial streets. Examples of the corresponding computational engines are called FREEVAL (for freeways) and STREETVAL (for urban streets), respectively, in addition to the commercially available Highway Capacity Software (HCS), which has procedures for both types of facilities. In freeway facility analysis, a freeway facility is divided into four types of segments; including basic, merge, diverge, and weaving segments. When traffic is under congestion, segments are analyzed independently. Depending on the segment type, the corresponding HCM procedure is applied to calculate segment speed. When traffic is oversaturated, the freeway facility is analyzed as a node-link system and a cell transmission model is utilized to track queue formulation and dissipation over multiple time periods and segments. The output performance measures include travel time, speed, delay, queue length, VMT, VHT, and LOS for each individual segment.

In urban streets analysis, urban street facilities are coded as segments with boundary nodes that represent signalized or unsignalized intersections. The performance of segments is determined by first analyzing the segment running time and through movement delay based on the signal control information and segment free-flow speed, and then calculating the segment travel speed, stop rate, and level of service. The level of service of a signalized intersection is determined based on the control delay. The travel time along a segment can be derived from segment travel speed.

### 4.1.2.4 Simulation Modeling

Macro-, meso-, and micro-level simulation models can be applied to obtain travel time along a segment or a route. However, these models vary in terms of the details of network and driving behaviors, data requirements, and the effort required to develop and more importantly to calibrate the models. Macroscopic models (for example, regional travel demand models) consider vehicles as a whole and utilize traffic flow model to determine the traffic condition on a link or section. Microscopic simulation provides a detailed modeling of road network. Individual vehicle movements are governed by car-following, lane changing, and gap acceptance behaviors. However, microscopic modeling requires significantly more efforts to calibrate. Examples of microscopic models are VISSIM, CORSIM, PARAMICS, AIMSUN, and TransModeler. Mesoscopic simulation models are in between macroscopic and microscopic simulations. In mesoscopic model, vehicles are modelled either individually or as packets of a small number of vehicles. However, the movements of vehicles or packets of vehicles are determined by the macroscopic traffic flow models. The queuing and queue spillback are usually captured by considering the constraints of capacity and link storage. Compared to microscopic simulation,
Mesoscopic simulation requires less effort to calibrate and has a faster running time. Examples of mesoscopic simulations are Dynasmart, DynusT, Direct, Cube Avenue, AIMSUN, VISSIM meso, and Dynameq.

4.1.2.5 Queuing Theory

Queuing occurred when the number of arriving vehicle (e.g. demand flow rate) becomes greater than the roadway segment capacity within a particular time period. Queuing measures such as queue lengths and associated delays can be estimated using analytical models such as queuing theory based on the cumulative volume and shockwave theory. When comparing queuing and shock wave analysis, queuing analysis is used more widely to identify congestion impacts due to its simplicity. A study by Rakha and Zhang (2005) demonstrated the consistency in delay estimates based on queuing theory and shock-wave analyses and pointed out that queuing theory provides a simple and accurate technique for estimating delays and queue lengths at bottlenecks. Thus, this study will investigate the use of queuing theory to calculate the delay at locations when the volume exceeds capacity.

The number of vehicles in queue can be estimated using Equation 4-6.

\[ N_{qi} = V_{ai} - V_{di} + N_{q(i-1)} \]  

(4-6)

where \( N_{qi} \) is the number of queued vehicles at the end of period i, \( V_{ai} \) is the number of arriving vehicles during period i, \( V_{di} \) is the roadway segment capacity, and \( N_{q(i-1)} \) is the number of vehicles queued at the end of period (i-1).

To estimate the queuing delay, there is a need to estimate the difference between demand and capacity for each time period where queue exists. Next, the average vehicle delay for each time period can be identified from the ratio between the area formed by cumulative demand vs. cumulative capacity curve and actual volume for that time period (a simple example is shown in Figure 4-1). Finally, the queuing delay can be accounted for to estimate actual travel time (or speed) for each time period.

![Figure 4-1: Queuing Delay Estimation Approach](image)
4.1.3 Comparison of Traffic Flow Models for Travel Time Estimation

Different methods to estimate travel time and travel time reliability were assessed by comparing the resulting estimates from applying these methods to those estimated based on real-world data. Two corridors were used as case studies for assessing the accuracy of the estimates for freeways and urban arterial streets, respectively, as follows:

- I-95 northbound between NW 32nd Street and NW 103rd Street in Miami-Dade County, FL (used as a freeway case study)
- Sunrise Blvd. between US 441 and US 1 in Broward County, FL (used as an urban street case study)

4.1.3.1 The Freeway Case Study

A 4.73 mile (24,977 feet) long freeway roadway segment along the I-95 Northbound (NB) was selected for use as a freeway case study. This segment is instrumented with six microwave point detection stations, starting from NW 32nd Street to NW 103rd Street, as shown in Figure 4-2. Prior studies suggest that NW 103rd Street on-ramp merge is a bottleneck to the I-95 NB traffic. Thus, this location was selected as the downstream capacity constrained location. The study corridor was selected such that the detector on the upstream end remains uncongested during the study period to ensure that all queues and demands are accounted for as much as possible. When the volume exceeds the estimated capacity of the segment, the demand at the queuing location was estimated by adding the queue length increment in a period to the volume in that period, since the volume by itself is constrained by the capacity and does not represent the demand in congested conditions. Figure 4-2 shows the detector number (green color) and the distance covered by each detector. As shown in the figure, Detector No. 2876 is located near NW 103rd Street and Detector No. 3016 is located near NW 32nd Street. The traffic flow direction is from NW 32nd Street (Detector No. 3016) northbound to NW 103rd Street (Detector No. 2876).

![Figure 4-2 Detector Locations and Coverage Along the I-95 NB (Freeway Corridor)](image)

4.1.3.2 The Arterial Street Case Study

Sunrise Blvd. from US 441 up to US 1 in the Eastbound (EB) direction was selected as the arterial case study. The length of this segment is around 5.3 miles and includes seven detection stations that provide volume and speed measurements. Figure 4-3 shows the detector number (green color) and the distance covered by each detector. As shown in the figure, Detector No. 9 is located near US 441 and Detector No. 15 is located near US 1. The traffic flow direction is eastbound, from US 441 to US 1. Bluetooth readers are also installed on this segment to derive travel time measurements.
4.1.3.3 Data Collection and Preparation

This study performed extensive data analysis to measure mobility and reliability based on real-world data for comparison with the different utilized methods. To do that, one-year worth of volume and speed/travel time data were gathered for both the freeway and arterial facilities. Traffic incident and weather condition data for the corresponding year were also obtained for both facilities.

**Overview of Freeway Data**

Three important freeway parameters were required for this study to estimate the mobility measures based on data for the freeway case study, as follows:

- Traffic parameters (volume and speed data),
- weather data, and
- incident data.

Volume data was needed for this study to measure demand, while speed data was required to estimate travel time. This study gathered volume and speed data from the RITIS data warehouse (Regional Integrated Transportation Information System) website. The weather data (rainfall intensity) was used in the estimation of reliability based on modeling. The rainfall intensity information was collected from NOAA (National Oceanic and Atmospheric Administration).

This study also obtained incident data for utilization in the estimation of reliability. Detail incident data were collected from the FDOT District Six database to calculate the number of incidents during a time slice, average number of lane blockage per incident, and average duration of each incident.

For this study locations, three different time periods have been included in the analysis:

- AM Peak (07:00 AM – 09:30 AM),
- Mid-Day (12:00 PM– 02:30 PM), and
- PM Peak (02:30 PM – 04:30 PM)

**Overview of Arterial Street Data**

To estimate different mobility measures, the following traffic measurements were obtained in this study:

- Volume data from microwave point detectors (MVDS),
- Travel time data based on Bluetooth readers installed by FDOT District 4 and two private sector vendors (Inrix and HERE),
• Turning movement counts from a previously well calibrated VISSIM network for use as inputs to the HCM procedure,
• Traffic signal timing data from the well-calibrated network, and
• Incident data.

Similar to the freeway, this study also estimated reliability utilizing incident data. Detail incident data were collected from the FDOT District 4 SunGuide system to determine the number of incident during a time slice, average number of lane blockage per incident, and average duration of each incident. The incident data was used as an input to the HCM procedure and to estimate the LHL required for SHRP2 L03 and SHRP2 L07 projects.

Three different time period has been also considered for arterial corridor analysis:
• AM Peak (07:00 AM – 09:00 AM),
• Mid-Day (11:00 AM – 01:00 PM), and
• PM Peak (04:00 PM – 07:00 PM)

**Volume and Speed/Travel Time Data**

Volume and Speed/travel time data were collected from the RITIS website for the selected freeway corridor. For the freeway segment, the downloaded RITIS data includes volume, speed, and occupancy measurements using point detectors and travel time using HERE data. For the arterial segment, travel time data from Bluetooth readers and two private sector data vendors (HERE and Inrix), in addition to volumes from microwave detectors, were also downloaded from RITIS.

The investigation of forecasting travel times using different models was based on data for the period between January 1st, 2017 and December 31st, 2017. On the freeways (I-95 NB), only measurements based on the detectors on general-purpose lane and nly weekdays were used in the analysis. Data for incident days was also collected but removed from the database when estimating mobility for recurrent conditions. Incident day comparison was also conducted later. For the analysis purpose, this study aggregated the downloaded 5-minute data into three-time periods; the AM, Mid-Day, and PM periods. To better understand the model performance, the mobility comparison was performed for ten randomly selected days, instead of averaging the days over the full year.

For reliability estimation on the freeway, the speed and volume data were gathered for the same freeway corridor from an earlier period (1st January 2012 – 31st December 2012) SHRP2 pilot test project and also for the Year 2017. The reason for selecting the earlier period is that it was used for a detailed investigation of reliability estimation as part of a SHRP2 project conducted by the authors. Like mobility, only weekday data was considered for reliability estimation. Incident day data was also included in the reliability analysis, as the incident is a key contributing factor in a reliability study.
**Weather Condition Data**

This study requires weather condition data (e.g. rainfall intensity) to measure reliability. Rainfall intensity information was obtained from NOAA for the year 2012 as this study utilized 2012 data for reliability estimation and also for 2017.

**Traffic Incident Data**

Traffic incident data is also required in this study to estimate reliability. Since this study measured reliability for both freeway and arterial segments, incident data were collected for both facilities.

Traffic incident data for the I-95 NB facility was collected from the FDOT District Six and RITIS website. The traffic incident data for the arterial segment (Sunrise Blvd.) was collected from the FDOT District 4 SunGuide system database. Incident data was gathered for the same periods as those, for which the traffic and weather data were collected. The FDOT traffic incident data provides detailed incident information for every incident. From the incident database, the following information was extracted and utilized in this study.

- Number of incidents
- Average number of lanes blocked per incident
- Average duration of incidents

Since this study analyzed data in 3 specific time slices (AM, Mid-Day, and PM), each of the above information was estimated for each time slice.

**Traffic Signal and Capacity Data**

This study estimated mobility and reliability on arterial for which traffic signal timing and capacity data were needed. A previously well-calibrated VISSIM network for Sunrise Blvd. was utilized in this study to obtain turning movement volume and traffic signal timing information (offset, green time, and cycle length). Traffic signal timing information for each of the intersection along the EB Sunrise Blvd. corridor was extracted from the VISSIM network. The cycle length was found to be 180 sec. for all intersections. The effective green times for the EB main street through movement on individual intersections vary from intersection to intersection between 93 seconds and 145 seconds. The timing information was used as an input to the Urban Street module of the Highway Capacity Software (HCS) and also to calculate the capacity for use in traffic flow equation calculation of travel time on arterial streets. The effective green time and cycle length information were utilized to derive arterial roadway capacity using Equation 4-7.

\[
\text{Capacity} = \frac{\text{Effective Green Time}}{\text{Cycle Length}} \times 1700 \tag{4-7}
\]

Five different capacity was used in the traffic flow functions (BPR curve, Akcelic equation, etc.) as follows:

- 900 vehicles per hour per lane – this is the value used in the SERPM demand model for the Sunrise Blvd.
• 880 vehicles per hour per lane - This value was obtained from Equation (4-7) by taking the minimum value of the effective green time to cycle length ratio among all the intersections along the EB direction of Sunrise Blvd.
• 1,120 vehicles per hour per lane – This value was obtained from the Equation (4-7) by taking the average value of the effective green time to cycle length ratio among all the intersections along the EB direction of Sunrise Blvd.
• 1,370 vehicles per hour per lane - This value was obtained from the Equation (4-7) by taking the maximum value of the effective green time to cycle length ratio among all the intersections along the EB direction of Sunrise Blvd.

4.1.3.4 Freeway Recurrent Conditions Analysis Results

The accuracy of the following functions to estimate speed/travel time were assessed based on comparison with data-based estimates of travel time:

• Bureau of Public Road (BPR) Curve with the parameters extracted from SERPM
• Akcelik Equation with the parameters extracted from the ELTOD software developed for managed lane toll assessment
• BPR Curve with the parameters calibrated in a study conducted by Florida State University (FSU)
• Akcelik Equation with the parameters calibrated in a study conducted by FSU
• Modified Davidson Equation with the parameters calibrated in a study conducted by FSU
• Conical Equation with the parameters calibrated in a study conducted by FSU
• Freeway and urban street Highway Capacity Manual (HCM) procedures

Figures 4-4 to 4-6 present the speed estimates for the AM Peak period, which is a non-congested peak since the northbound traffic is the non-peak direction. The figures provide a comparison between the estimates obtained using different mobility estimation methods compared to real-world measurements using detector data (referred to as Detector Speed in the figures) and HERE data (referred to as Prob Speed in the figures). Please, note that a disadvantage with the probe data is that it does not differentiate between general purpose and managed lane speed. Estimates from only three of the ten selected days since this is sufficient to discuss the findings. The days were selected to represent different seasons of the year 2017; early year (February 7, 2017), mid-year (June 22, 2017), and end of the year (December 12, 2017). Tables 4-3 and 4-4 present goodness of fit statistics to illustrate the performance of different methods. Based on the comparison, it appears that several methods predicted speeds reasonably well compared to real-world mobility measures for the uncongested NB direction of the freeway in the AM Peak period. The Conical model did not perform well showing higher percentage error. The methods with the highest accuracy were FSU-calibrated Modified Davidson FSU-Calibrated and ELTOD Akcelik function, highway capacity procedure utilizing FREEVAL, and FSU calibrated BPR curve. It should be mentioned that for uncongested conditions, it is expected that the estimation accuracy improves by better estimation of free flow speed. The free flow speed used as input to the models was calculated as the posted speed limit (55 mph) plus 5 mph.

Figures 4-7 to 4-9 present the speed estimation accuracy for the mid-day period, which is uncongested period. As with the AM period, the figures present the results for three days of the selected 10 days. Tables 4-5 and 4-6 present goodness of fit statistics to illustrate the performance of different methods. The accuracy analysis results in the mid-day appear to be very similar to that in the AM period, with most function perform relatively well. The Conical model did not perform well. The FSU-calibrated Modified Davidson, the default Akcelik used in ELTOD, highway capacity procedure in FREEVAL, and FSU calibrated BPR curve performed the best, as in the AM peak.

Figures 4-10 to 4-12 present the speed estimation accuracy for the PM peak period, which is a congested period. As with the AM period, the figures present the results for three days of the selected 10 days. Tables 4-7 and 4-8 present goodness of fit statistics to illustrate the performance of different methods. The figures and tables indicate that it is more difficult to predict the travel time accurately in the PM congested period. Some of the tested functions produced high errors. The functions that produced the best results are the FSU-calibrated Modified Davidson, the Akcelik function used in ELTOD, the default BPR curve used in SERPM, and the FREEVAL (freeway facility HCM-based facility procedure).

Based on the results presented in this section, the functions that produced the best results for all three periods for the ten days are the FSU-calibrated Modified Davidson model, the Akcelik function used in ELTOD, and the HCM-based freeway facility procedure. The SERPM BPR relationship worked well for congested conditions but was somewhat less accurate than other methods for uncongested conditions. The other tested models were less accurate. In general, the estimation is much more accurate for less congested conditions for all tested methods.

4.1.3.5 Calculation of Other Mobility Measures based on Travel Time Estimates (Freeway)

Mobility measurements listed in Table 4-1, as required by national and state guidance and procedures can be calculated based on travel time estimates calculated as described above combined with demand model output. Table 4-9 provides a summary of such measurements for the I-95 corridor segment used as a freeway case study segment in this project.

4.1.3.6 Freeway Incident Conditions Analysis Results

This study further investigated the predictive ability of the different methods in presence of an incident during the AM peak, which is uncongested in the NB direction of the freeway study segment during recurrent conditions. A real-world incident that occurred on March between 08:00 AM to 08:30 AM near NW 103rd Street was used in the comparison. The capacity due to the incident was adjusted accordingly based on the HCM procedure. Table 4-10 presents the performance summary of mobility estimation methods during incident.

</tr>
</tbody>
</table>
According to the Table 4-10, the lowest error was observed when using the ELTOD Akcelik model and the FSU-Calibrated Davidson model. The HCM procedure predicted higher travel time compared with the real-world measures. This model performs well for the PM congested conditions. Further examination indicates that the traffic in the HCM-based procedure takes longer time to recover from congestion caused by the incident. This could be due to not considering diverted traffic in the analysis.

It should be noted her that all models, except the Queueing Analysis and HCM-based procedure show that the delay occurs during the incident lane blockage duration and do not include the additional delay during queue dissipation (recovery) after incident lane-blockage clearance (see Figure 4-13). However, both the Queueing Analysis and HCM-based procedure overestimates the time it takes for the queue to recover. This may be due to underestimation of the queue discharge rate or an error in the incident duration estimation. This issue is being investigated.

![Figure 4-13: Incident Impact on Predictive Ability of Different Mobility Estimation Methods (Near 103rd Street)](image)

### 4.1.3.7 Arterial Recurrent Conditions Analysis Results

For arterial recurrent condition analysis, the eastbound direction of Sunrise Blvd. in Broward County from I-95 intersection to US1 was used as a case study location for the analysis. A year worth of traffic data was utilized to generate the results. Real-world travel time data from a private sector data provider (HERE) was used as the ground truth for evaluating the estimation performance of different predictive models.

The free flow speed ($S_f$) for an entire corridor was calculated following the procedure mentioned by Dowling, R. (1997). The free flow speed ($S_f$) is a function of length of the analysis segment (L), posted speed limit ($S_p$), Number of signalized intersections along the corridor (N), and total signal delay per vehicle (D).
where, \( C \) is the cycle length, \( g/C \) is the critical effective green time, cycle length ratio with a default value of 0.45, and \( DF \) is the delay adjustment factor (DF) which has the following default values:

- Uncoordinated traffic with actuated signals = 0.9
- Uncoordinated traffic with fixed time signal = 1.0
- Coordinated traffic with unfavorable progression = 1.2
- Coordinated traffic with favorable progression = 0.9
- Coordinated traffic with highly favorable progression = 0.6

The capacity is calculated using following equation:

\[
\text{Capacity (vph) = Ideal Sat} \times N \times F_w \times F_{HV} \times PHF \times F_{park} \times F_{ba} \times F_{CBD} \times g/C \times F_c
\]

\[
F_{HV} = 1/(1+HV)
\]

For this study location, the corridor has posted speed limit of 45 mph, length of the corridor is 1.8 mile and the traffic is coordinated with unfavorable progression. It has three through lanes with a lane width of 11ft, no presence of on-street parking and exclusive left turning lanes. Therefore, the equations provide a free flow speed of 28.3 mph and capacity of 662.6 vphpl. This is lower than the default capacity used in the SERPM model, which was 900 vphpl.

The estimated capacity (662 vphpl) is much lower than value used as default in the SERPM model (900 vphpl). Therefore, the above procedure was repeated utilizing the capacity of 900 vphpl. Figure 4-17 to 4-19 shows the actual travel time and model estimation travel time for the AM, PM, and Mid-Day periods. All the figures show that the use of 900 vphpl capacity underestimate the travel time especially during congestion. This appears to be mostly true when the
corridor is long with multiple signalized intersection within it. The use of lower capacity accounts for the arrival on red. Thus, the use of the lower capacity value of 662 vphpl is recommended.

Figure 4-17: Predictive Ability of Different Mobility Estimation Methods - Travel Time (Arterial, AM Peak, Capacity 900 vphpl)
Figure 4-18: Predictive Ability of Different Mobility Estimation Methods - Travel Time (Arterial, Mid-Day, Capacity 900 vphpl)

4.1.3.8 Calculation of Other Mobility Measures based on Travel Time Estimates (Arterial)

Mobility measurements listed in Table 4-1, as required by national and state guidance and procedures can be calculated based on travel time estimates calculated as described above combined with demand model output. Table 4-12 provides a summary of such measurements for the Sunrise Blvd. segment used as an urban street case study segment in this project.

4.2 Reliability Performance Measure

The travel time reliability measures reflect day-to-day variation in congestion levels due to contributing factors such as demand and capacity stochasticity, incidents, adverse weather, and work zones. This section describes different reliability measures, the methods utilized to estimate them, and presents a comparison of these method accuracy based on the project case study data.

Table 4-13 presents the commonly used reliability measures. These measures are estimated based on travel time data. The data should be for at least one-year period. The contributing factors to the unreliability of the system requires the collection of volume, incident, weather, and work zone data. Reliability can also be estimated based on models that range from simple equations to HCM-based procedures to simulation-based procedures. The methods to estimate reliability based on data and models are described next.

In this study, the forecasting of reliability measures was compared with reliability estimations for both the freeway case study (I-95 in Miami-Dade County) and the arterial segment (Sunrise Blvd. in Broward County) based on real-world data from Bluetooth vendors and two data vendors (HERE and INRIX). The followings are the tested reliability forecasting methods in this project, all of which developed as part of the Reliability Program of the Strategic Highway Research Program 2 (SHRP2):

• SHRP2 L03 Project Data-Poor Procedure
• SHRP2 L03 Project Data-Rich Procedure
• SHRP2 L07 Project Procedure with Default Parameters
• SHRP2 L07 Project Procedure Calibrated for Miami by Florida International University as part of the SHRP2 L38 project
• SHRP2 C11 Project Procedure
• SHRP2 C11 Project Procedure Calibrated for the Tampa Bay Region as part of a federal grant
• SHRP 2 L08 procedures as adopted in the HCM and implemented in FREEVAL and HCS.

4.2.1 Forecasting of Reliability Performance Measures

4.2.1.1 SHRP 2 L02 Method

The Strategic Highway Research Program 2 (SHRP2) SHRP2 L02 project provides a framework and guidance for a data-based travel time reliability estimation method (Institute for Transportation Research and Education et al., 2012). The framework consists of three components, that is, a data manager, a computational engine, and a report generator. The data manager assembles data from traffic sensors, weather data feeds, and incident reporting systems, and organizes them in a database. The computational engine classifies traffic into different regimes based on demand, incident, and weather. The probability density function (PDF) and cumulative density function (CDF) distributions of travel time rate for each regime are calculated from the collected and cleaned data. These two distributions allow the visualization and comparison of travel time reliability under various traffic conditions as well as the identification of contributing factors to unreliability. The report generator presents results based on user requests.

4.2.1.2 Highway Capacity Manual Procedure

The SHRP 2 Project L08 developed reliability assessment methods and tools based on the Highway Capacity Manual (HCM) freeway and urban street facility procedures and computational engines (Kittleson & Associates et al. 2012). These procedures were used a basis for reliability estimation in the latest version of the HCM. The FREEVAL-RL, STREETVAL-RL, and Highway Capacity Software (HCS) apply the above mentioned developed procedures to estimate travel time reliability. These tools have a scenario generator, which takes the input of demand, weather, incident, and work zone data, and generates a set of scenarios that represent different traffic conditions that are expected to occur within one year along the study facility. The impacts of incident, weather, and work zone events on capacity and speed are adjusted by using adjustment factors recommended by HCM. The conventional HCM computational engine for freeway or urban street facility is then utilized to calculate the travel time for each scenario. The measures of travel time reliability, including standard statistical measures (e.g., standard deviation, kurtosis), percentile-based measures (e.g., 80th and 95th percentile travel time, buffer index), on-time measures (e.g., percent of trips completed within a travel time threshold), and failure measures (e.g., percent of trips that exceed a travel time threshold), are calculated from the resulted distribution of travel time.
4.2.1.3 SHRP2 L03 Method

As a foundational study, the product of the SHRP2 L03 project defined reliability, presented recommended reliability measures derived from travel time distributions, highlighted the causes of congestion, explained how to build a database for estimating reliability prediction models, conducted before and after studies of operations and capacity improvements, and developed two sets of prediction models based on empirical data from numerous metropolitan areas (Cambridge Systematics et al., 2013). SHRP2 L03 gathered a year worth of readily available real-world detector-based travel time data from transportation agencies/private sectors for different regions of the United States. The study adopted a before-after study approach to build the relationship between highway improvements and travel time reliability. SHRP2 L03 developed two cross-sectional statistical predictive models to capture the relationship in context of highway improvements; ‘data-poor model’ and ‘data-rich model’.

Data-Poor Model

The SHRP2 L03 produced a highly practical set of relationships to predict reliability, known as ‘data-poor’ model. The data-poor model is a simpler model that can be applied in an environment with limited data. The calculation equations are provided below.

Overall mean TTI= 1.0274*RecurringMeanTTI^{1.2204} \hspace{1cm} (4-13)

95th Percentile TTI = mean TTI^{1.8834} \hspace{1cm} (4-14)

90th Percentile TTI = mean TTI^{1.6424} \hspace{1cm} (4-15)

80th Percentile TTI = mean TTI^{1.365} \hspace{1cm} (4-16)

Median TTI = mean TTI^{0.8601} \hspace{1cm} (4-17)

10th Percentile TTI = mean TTI^{0.1524} \hspace{1cm} (4-18)

The above equations work when the mean TTI is less than 2. However, in many cases, the mean TTI may exceed 2. Equation 4-19 to Equation 4-21 should be used for mean TTI greater than 2.

95th percentile TTI = 1+3.6700 *In (Mean TTI) \hspace{1cm} (4–19)

90th percentile TTI = 1+2.7809 *In (Mean TTI) \hspace{1cm} (4–20)

80th percentile TTI = 1+2.1406 *In (Mean TTI) \hspace{1cm} (4–21)

Data-Rich Model

The project L03 quantifies the impact of incidents and work zones on reliability with respect to three key variables; a) lane hours lost, b) critical demand-to-capacity ratio, and c) hours of rainfall exceeding 0.05 inch. The relationship is provided below.

\[ TTI_{n\%} = e^{(j_n d_{crit} + k_n LHL + l_n R_{0.05})} \hspace{1cm} (4-22) \]

where TTI_{n\%} is nth percentile travel time index. Depending on the coefficients used in Equation 4-22, different percentile of travel time index can be estimated. LHL is the lane hour lost due to incidents and work zone. This value is calculated as the average number of lanes blocked per incident or work zone multiplied by the average duration of incident or work zone and the total
number of incidents/work zones within the study time period and study time slice. $d_{crit}$ represents the critical demand-to-capacity ratio. Two methods were recommended to calculate demand. In the first method, when there is no congestion, the 30th-highest volume count during one-year weekdays is used as the demand. However, as traffic detectors measure volume counts instead of demand during the congested periods, a demand has to be either estimated by using a cumulative volume-based method proposed by the L03 project or by adding a field-observed number of vehicles in queue for congested periods. When there is only a single-day or multiple-day collection of volume counts, these limited volume counts are converted to the counts in the peak month using a seasonal factor and a weekday adjustment factor.

The parameter $R_{0.05}$ in Equation 4-22 is the hours of rainfall with a precipitation greater than 0.05 inch during the time slice and study period. The remaining variables in Equation 4-22 are regression coefficients, whose values are listed in Table 4-14.

4.2.1.4 SHRP2 L07 Method

The SHRP2 L07 project developed a sketch planning-level tool for assessing the impacts of highway design treatments on travel time reliability (Potts et al., 2014). The product of the SHRP 2 L07 is a design guide, consisting of a compendium of design treatments likely to affect non-recurring congestion plus an Excel-based tool that designers can use to evaluate the effects of such treatments on delay, safety, travel time reliability, and lifecycle benefits and costs (Potts et al., 2014). As stated earlier, SHRP2 L03 developed models for predicting a travel time index (TTI) at five percentiles (10th, 50th, 80th, 95th, and 99th) along the TTI distribution, but only for certain peak periods (e.g. AM Peak, PM Peak). The SHRP2 L07 research team adapted a modification to the SHRP2 L03 data-rich models for use for one-hour time-slices, so that the TTI distribution could be predicted for each hour of the day. The coefficients corresponding to the Equation 4-23 are presented in the Table 4-15.
\[
TTL_n = \begin{cases} 
TTL_{NP,n} \times e^{(c_n R_{05'} + d_n S_{01'})} & \text{for } d/c \leq 0.8 \\
N_{NP} + V_{FF} \left( \frac{R_{05'}}{c_1 V_{FF} + c_2 TTL_{NP,n}} + \frac{S_{01'}}{d_1 V_{FF} + d_2 TTL_{NP,n}} \right) & \text{for } d/c > 0.8 
\end{cases}
\]

Table 4-15: Default coefficients for L07 data-rich model

A study by Jia et al. (2014) found that the Travel Time Index (TTI) produced by the above equations are more sensitive to the number of incidents and incident duration than other factors such as demand and weather. The predicted TTI value using Equation 4-23 also has a large difference from that calculated based on real-world data. Therefore, a similar regression procedure was utilized by Jia et al. (2014) to derive expressions for travel time indices based on data for I-95 in Miami, FL. Equation 4-24 shows the final expressions and the parameters in this equation are listed in Table 4-16.

\[
TTI_{NP,n} = e^{b_1 + dc_{crit} + b_2 + LHL + b_3 + Rain + b_4 + Length + b_5} + b_6
\]

Table 4-16 Coefficients Developed by Jia et al. (2014)

4.2.1.5 SHRP2 C11 Method

The SHRP2 C11 aimed at improving the state of the practice in assessing the wider economic benefits of transportation capacity projects. Three classes of project benefits were addressed in project C11: a) travel time reliability benefits, b) intermodal connectivity benefits, and c) market access benefits. The travel time reliability benefits were estimated in the SHRP2 C11 using the following steps:

**Step 01: Free Flow Speed Estimation**

For freeways and rural two-lane highways,

\[
\text{Free Flow Speed} = (0.88 \times \text{Speed Limit}) + 14
\]

(4-25)
For signalized highways,

\[
\text{Free Flow Speed} = (0.79 \times \text{Speed Limit}) + 12
\]  
(4-26)

**Step 02: Travel Time per Unit Distance (Travel Rate) for the Current and Forecast Years**

\[
t = \left[\left(1 + \left(0.1225 \times \left(\frac{v}{c}\right)^8\right)\right)\right]/\text{Free Flow Speed, for } \frac{v}{c} \leq 1.40
\]  
(4-27)

where, \(t\) is the travel rate (hours per mile), \(v\) is hourly volume; and \(c\) is the capacity. Please note that, the \(v/c\) value is capped at 1.4.

**Step 03: Delay Due to Incidents (Incident Delay Rate) in Hours per Mile**

\[
D_a - D_u \times \left(1 - R_f\right) \times \left(1 - R_d\right)^2
\]  
(4-28)

where, \(D_a\) is the Adjusted delay (hours of delay per mile); \(D_u\) is Unadjusted (base) delay (hours of delay per mile, from the incident rate tables); \(R_f\) is Reduction in incident frequency expressed as a fraction (with \(R_f = 0\) meaning no reduction, and \(R_f = 0.30\) meaning a 30% reduction in incident frequency), \(R_d\) is Reduction in incident duration expressed as a fraction (with \(R_d = 0\) meaning no reduction, and \(R_d = 0.30\) meaning a 30% reduction in incident duration).

**Step 04: Compute the Overall Mean Travel Time Index (TTI<sub>m</sub>)**

\[
TTI_m = 1 + \text{FFS} \times (\text{Recurring Delay Rate} + \text{Incident Delay Rate})
\]  
(4-29)

\[
TTI_{95} = 1 + 3.6700 \times \ln(TTI_m)
\]  
(4-30)

\[
TTI_{50} = 4.01224/\{(1 + e^{(1.7417 - 0.93677 \times TTI_m)/(1/0.8274)})\}
\]  
(4-31)

\[
TTI_{80} = 5.3746/\{(1 + e^{(-1.5782 - 0.85867 \times TTI_m)/(1/0.0495)})\}
\]  
(4-32)

The SHRP2 C11 Project reliability models predicts reliability measures as a function of the Mean Travel Time Index (MTTI) for a segment.

Later, a SHRP2 C11 Post-Processor tool was developed under a Florida Department of Transportation (FDOT) (Cambridge Systematics, Inc., 2016) contract in conjunction with the Hillsborough County MPO in Tampa, Florida. To develop reliability prediction equations for Florida, the C11 Post-Processor tool mentioned above obtained travel data for the Tampa region from the National Performance Management Research Data Set (NPMRDS) for 2014 and 2015. In the analysis, the segments were defined based on the Traffic Message Channels (TMCs) location referencing scheme, which is the basic geographic reporting unit (link) in the NPMRDS data.

The following equations were derived for Travel Time Index (TTI) for freeways:

\[
TTI_{50} = 10.4910 - 9.5867 \times e^{(-0.0142 \times X^{2.2367})} \text{ for } X > 1.07
\]
\[ TTI_{50} = 0.963X + 0.037 \quad \text{otherwise} \quad (4-33) \]

\[ TTI_{80} = 7.3567 - 6.9965 \times e^{(-0.0910 \times X^{2.0185})} \quad \text{for} \ X > 1.03 \]

\[ = 1.0 \quad \text{otherwise} \quad (4-34) \]

\[ TTI_{95} = 11.7933 - 16.2178 \times e^{(-0.3855 \times X^{1.0336})} \quad \text{for} \ X > 1.08 \]

\[ = 1.3737X - 0.3737 \quad \text{otherwise} \quad (4-35) \]

where, \( X \) is Mean Travel Time Index (MTTI); \( TTI_{50} \) \( TTI_{80} \), and \( TTI_{95} \) are 50th percentile, 80th percentile, and 95th percentile TTI respectively.

The following equations were used to derive TTI for signalized arterials:

\[ TTI_{50} = \frac{0.9333 \times 101.7049 + 12.887 \times X^{2.403}}{101.7049 + X^{2.403}} \quad \text{for} \ X < 1.07 \]

\[ = X \quad \text{otherwise} \quad (4-36) \]

\[ TTI_{80} = \frac{0.7266 \times 26.26 + 9.6702 \times X^{2.5698}}{26.26 + X^{2.5698}} \quad (4-37) \]

\[ TTI_{95} = 21.1669 \times e^{\frac{-2.9506}{X}} \quad (4-38) \]

The following steps were used to calculate the MTTI:

\textbf{Step 01: Assign Free Flow Speed (FFS)}

Free Flow Speed (FFS) for freeway in Tampa was set at 60 mph, for arterial streets at 45 mph, for collectors at 35 mph, and for other types of road at 30mph.

\textbf{Step 02: Calculate the Recurring Delay Rate (hours per vehicle-mile)}

Recurring Delay Rate = \( \frac{1}{\text{Speed}} \) – \( \frac{1}{\text{FFS}} \) \quad (4-39)

\textbf{Step 03: Calculate the Base Incident-Related Delay Rate (hours per vehicle-mile)}

Number of lanes <= 2:

\[ Du = -0.0111/(1 - 1471 \times \exp^{-6.8498 \times v/c}) \quad (4-40) \]

Number of lanes = 3:

\[ Du = -0.0085/(1 - 1872 \times \exp^{-7.1381 \times v/c}) \quad (4-41) \]

Number of lanes >= 4:

\[ Du = -0.0068/(1 - 1827 \times \exp^{-7.1090 \times v/c}) \quad (4-42) \]

Where, \( Du \) is the base incident delay rate and \( v/c = \text{volume-to-capacity ratio} \).
**Step 04: Calculate the MTTI**

\[ \text{MTTI} = 1 + (\text{FFS} \times (\text{Recurring Delay Rate} + \text{Du})) \]  

(4-43)

4.2.2 Comparison of Reliability Measure Calculation Methods

This section provides the results of the application of the SHRP2 products (L03, L07, C11, and HCM-based procedure) to estimate reliability measures (e.g. travel time index) for both freeway and arterial facilities. The study considered three forms of the travel time index as reliability measures: the 80th percentile, the 90th percentile, and 95th percentile travel time indexes. This section also includes a comparison of these estimated reliability measures and the reliability measures estimated based on real-world. Please note that the HCM-based analysis is on-going. Thus, only partial results from applying this procedure are presented in this memorandum. Additional details will be presented in a future deliverable.

4.2.2.1 Freeway Reliability

Figures 4-20 to 4-22 and Table 4-17 present the reliability measures (e.g. travel time index) for the freeway case study corridor during the AM Peak, Mid-Day, and PM Peak periods. As mentioned before, the study estimated three set of reliability measures (the 50\(^{th}\) percentile TTI, 80\(^{th}\) Percentile TTI, and 95\(^{th}\) percentile TTI) and compared the estimated measures with real-world measures, as shown in the figures. As presented in the figures, the estimated reliability measures were found to be very close to the real-world measures for the AM Peak and Mid-Day periods. However, the estimated reliability measures were different than the real-world measures during the more congested PM Peak for all three indices (50th percentile TTI, 80th Percentile TTI, and 95th percentile TTI). When considering the three peaks, the models that produced the best forecasts of reliability compared to data-based reliability estimation for the freeway segment is the SHRP2 C11 model calibrated for the Tampa Bay Area and the SHRP2 L03 Data Poor Model. Please note that the Akcelic Equation was used to generate the mean recurrent travel time for the models that require the estimation of this value.

4.2.2.2 Arterial Reliability

Figures 4-23 to 4-25 and Table 4-18 present the reliability measures (e.g., travel time index) for the arterial street case study corridor during the AM Peak, Mid-Day, and PM Peak periods. As with the freeway case study, the study estimated three set of reliability measures (the 50th percentile TTI, 80th Percentile TTI, and 95th percentile TTI) and compared the estimated measures with real-world measures, as shown in the figures. When considering the three peaks, the model that produced the best forecasts of reliability compared to data-based reliability estimation for the urban arterial study segment is the L07 original model followed by the SHRP2 L03 data poor and L03 data rich model.

4.3 Safety Performance Measure Estimation

Two methods can be used to estimate the safety performance for the base conditions: the Lookup Table method and the Florida Safety Performance Functions (SPF). As described later in this document, the updated version of FITSEVAL allows the user to estimate the safety for the base conditions using one of these two methods or based on real-world crash data.

4.3.1 Lookup Table

The first method to predict the number of crashes is the Lookup Table along a corridor method, which is based on the same method used in the original version of FITSEVAL (Hadi et al., 2008). Table 4-19 shows the crash rates per Million Vehicle Miles Traveled (MVMT) of...
property damage only (PDO), injury, and fatality for freeway and arterial segments as a function of Volume to Capacity (V/C) ratio, utilized in the method. The total number of crashes is then estimated by multiplying the crash rate by the MVMT (which is a multiplication of segment volume and length). The advantage of this method is that it can be directly applied to any period in the day as long as we know the average V/C ratio, the segment length, and the volume for the period. The disadvantage is that these relationships have not been fully and formally calibrated for Florida.

4.3.2 Florida Safety Performance Function

The second method utilizes calibrated SPFs developed for Florida based on roadway inventory data and crash data (Alluri et al., 2016). Equation 4-44 presents the general form of the SPF function used for roadway segments and ramps.

\[ N_{predicted} = e^a \times AADT^b \] (4-44)

where \( N_{predicted} \) is the number of predicted crashes per mile per year and AADT represents average annual daily traffic. \( a \) and \( b \) are regression coefficients.

Equation 4-45 presents the SPF functional form for intersections.

\[ N_{predicted} = e^a \times AADT_{major}^b \times AADT_{minor}^c \] (4-45)

where AADT\(_{major}\) and AADT\(_{minor}\) represent the average annual daily traffic for the major and minor approaches of an intersection, respectively. Symbols \( a \), \( b \), and \( c \) are regression coefficients.

Tables 4-20 to 4-23 present the coefficients of the calibrated SPF functions to estimate the total number of crashes and to estimate fatal plus injury crashes (F+I) for arterial streets, freeways, intersections, and ramps, respectively. The actual number of crashes are calculated by multiplying the results with crash modification factors that account for various segment or intersection attributes. The advantage of this method is that it is that these relationship have been
fully and formally calibrated for Florida. The disadvantage is that the SPFs are functions of the AADT and thus does not account for the variations in volumes during the day. In the FITSEVAL application, a method was used to calculate the AADT based on the hourly volumes to allow the use of the SPFs as described next. Please note that in the first version of FITSEVAL produced as part of this project, the SPFs are applied without utilizing location specific crash modification factors to account for the attributes of the facility since this will add a complexity that cannot be accommodated with this project resources. This can be incorporated in a future update to the tool.

</table>
To be able to use Equation 4-44, the AADT needs to be calculated from the link traffic hourly volume before utilizing the SPF equation. The user will have to provide a ratio of the analysis hour volume to the AADT ($R_{volume}/AADT$) and directional factor (D), which is the ratio of traffic in the peak direction as inputs. The AADT is then calculated from the link volume using Equation 4-41.

$$AADT = \frac{Volume}{(R_{volume}/AADT) \times D}$$

(4-46)

The number of crashes on the intersections along the corridor is calculated using Equation 4-45. Since cross street volumes are difficult to obtain based on Cube outputs, the updated version of FITSEVAL has defaults for the cross street AADT as percentages of the main street AADT. These defaults can be overridden by the user to calculate intersection crashes. The following are the required variables:

- Total number of major signalized intersections on the segment (two major streets intersecting each other’s) = $I_{major-sig}$
- Total number of minor signalized intersections on the segment (one major street intersecting a minor street) = $I_{minor-sig}$
- Total number of un-signalized intersections = $I_{unsig}$
- Percentage of Cross Street AADT to Main Street AADT for the Major Intersections (default 40%) = $AADT_{Ratio_{major-signalized}}$
- Percentage of Cross Street AADT to Main Street AADT for the Minor Intersections (default 20%) = $AADT_{Ratio_{minor-signalized}}$
- Percentage of Cross Street AADT to Main Street AADT for the Minor Intersections (default 10%) = $AAD-Ratio_{unsignalized}$

$N_{predict\_major\_sig}$, $N_{predict\_minor\_sig}$, and $N_{predict\_unsig}$ are the predicted number of crashes for the three types of intersections calculated using Equation 4-45. Finally, the total number of crashes along the corridor is calculated utilizing Equation 4-47.

$$N_{predict\_cor} = \sum_{l=1}^{k} N_{predict\_link} + I_{major\_sig} \times N_{predict_{major\_sig}} + I_{minor\_sig} \times N_{predict_{minor\_sig}} + I_{unsig} \times N_{predict\_unsig}$$

(4-47)

The predicted number of crashes from the SPF is for the whole day and both direction. Therefore, the peak hour directional crush number is calculated using Equation 4-48.

$$No\ of\ crash\ in\ the\ peak\ hour = N_{predict\_cor} \times R_{volume}/AADT \times D$$

(4-48)

### 4.4 Summary

Different methods to estimate travel time and travel time reliability were assessed in this by comparing the resulting estimates from applying these methods to those estimated based on real-world data. Two corridors were used as case studies for assessing the accuracy of the estimates for freeways and urban arterial streets, respectively, as follows:
The accuracy of the following functions to forecast speed/travel time were assessed based on comparison with data-based estimates of travel time:

- Bureau of Public Road (BPR) Curve with the parameters extracted from SERPM
- Akcelik Equation with the parameters extracted from the ELTOD software developed for managed lane toll assessment
- BPR Curve with the parameters calibrated in a study conducted by Florida State University (FSU)
- Akcelik Equation with the parameters calibrated in a study conducted by FSU
- Modified Davidson Equation with the parameters calibrated in a study conducted by FSU
- Conical Equation with the parameters calibrated in a study conducted by FSU
- Freeway and urban street Highway Capacity Manual (HCM) procedures

Based on the results presented in this study, the functions that produced the best results for all three periods are the FSU-calibrated Modified Davidson model, the Akcelik function used in ELTOD, and the HCM-based freeway facility procedure. The SERPM BPR relationship worked well for congested conditions but was somewhat less accurate than other methods for uncongested conditions. The other tested models were less accurate. In general, the estimation is much more accurate for less congested conditions for all tested methods.

The functions were also tested to estimate travel times during an incident condition. The lowest error again was observed when using the ELTOD Akcelik model and the FSU-Calibrated Davidson model. The HCM procedure predicted higher travel time compared to the real-world measures. This model, however, performs well for the PM congested conditions, which raises questions on why this high delay is estimated during incident conditions. Further examination indicates that the traffic in the HCM-based procedure takes longer time to recover from congestion caused by the incident. An investigation is being done to determine the impact of reducing the capacity drop and/or increasing the queue discharge rate on improving the HCM-based procedure. It should be noted here that all models, except the Queueing Analysis and HCM-based procedure show that the delay occurs during the incident lane blockage duration and do not include the additional delay during queue dissipation (recovery) after incident lane-blockage clearance.

The findings from this chapter suggest that the travel time forecasting methods are able to forecast travel time more accurately for freeways compared to arterial street facilities and for less congested periods, as reflected by the MAPE values. For the arterial street segment, the FSU-calibrated Modified Davidson model produced the most accurate results for the AM and PM peak periods. However, the BPR function in the SERPM model works better for the Mid-Day period. Overall, it appears that, for the arterial segment, the FSU-calibrated Davidson model performed the best, followed by the SERPM default BPR curve, followed by the ELTOD Akcelik equation.
The HCM procedures have the advantage of considering the temporal and spatial impacts of congestion since they consider the spillbacks between the roadway segments including ramps and the extended queue from one period to the next. However, these procedures require more time to prepare and fine-tune the model and the use of a software like FREEVAL, STREETVAL, or Highway Capacity Software (HCS).

Reliability Forecasting

In this study, the forecasted reliability measures were compared with reliability estimated for both the freeway case study (I-95 in Miami-Dade County) and the arterial segment (Sunrise Blvd. in Broward County) based on real-world data. The followings are the tested reliability forecasting methods in this project, all of which were developed as part of the Reliability Program of the Strategic Highway Research Program 2 (SHRP2):

- SHRP2 L03 Project Data-Poor Procedure
- SHRP2 L03 Project Data-Rich Procedure
- SHRP2 L07 Project Procedure with Default Parameters
- SHRP2 L07 Project Procedure Calibrated for Miami by Florida International University as part of the SHRP2 L38 project
- SHRP2 C11 Project Procedure
- SHRP2 C11 Project Procedure Calibrated for the Tampa Bay Region as part of a federal grant
- SHRP 2 L08 procedures as adopted in the HCM and implemented in FREEVAL and HCS.

When considering the three peaks, the models that produced the best forecasts of reliability compared to data-based reliability estimation for the freeway segment is the SHRP2 C11 model calibrated for the Tampa Bay Area and the SHRP2 L03 Data Poor Model. The model that produced the best forecasts of reliability compared to data-based reliability estimation for the urban arterial study segment is the SHRP2 L03 Data Rich model. It should be noted that the overall reliability of the arterial test corridor appears to be relatively good, which did not allow testing the model under congested conditions. The performance under more congested conditions is being considered now.
5. **ASSESSING THE IMPACTS OF ADVANCED TECHNOLOGIES**

This chapter describes methods to estimate the impacts of the transportation system management and operations (TSM&O) and intelligent transportation systems (ITS) applications that are implemented in the updated version of the FITSEVAL tool, produced as part of this project. These applications include adaptive signal control, transit signal priority, freight signal priority, Connected Vehicles (CV)-based support of speed adjustment to support arrival on green, CV-based support of signalized safety, CV-based support of unsignalized intersection safety, CV-based hazard warning, and the effect of automation. Please, note that there many other applications that could have been included. The above applications were selected for the initial implementation. Additional applications will be added in the future as needed. This chapter also presents an overview of the updated version of the FITSEVAL tool.

5.1 **Evaluation of Advanced Applications**

ITS evaluation tools require three types of parameters: 1) Outcome Performance Modification Parameters, 2) cost parameters, and 3) benefit dollar values. The original FITSEVAL development effort as part of the original FDOT research project that resulted in the development of FITSEVAL (Hadi et al. 2008) identified methods to evaluate different ITS applications, based on an extensive review of literature. Default benefit, cost, and dollar value parameters were identified for use in the conjunction with the developed methods. The ITS applications that can be evaluated in the original version of FITSEVAL are:

- Incident management
- Ramp metering
- Advanced traveler information systems
- Smart work zones
- Road weather information systems
- Managed lanes
- Signal control
- Emergency vehicle signal preemption
- Transit vehicle signal priority
- Advanced public transit system
- Highway advisory radio (HAR) and dynamic message signs (DMS)
- Transit information system
- Transit security systems
- Transit electronic payment systems

As stated earlier, a different set of ITS implementations are included in the updated version of FITSEVAL to focus the development effort as it is implemented in a new platform. A strong focus in the updated version is on the impacts of connected vehicles (CV) and automated vehicles (AV). However, the assessment of additional applications can be added to the tool as needed. The following are the applications evaluated in the new version:
• Adaptive signal control with and without connected vehicle (CV) support
• Transit signal priority with and without CV support
• Freight Signal priority with and without CV support
• Speed adjustment of CV to support arrival on green
• CV applications to support of signalized intersection safety
• CV applications to support unsignalized intersection safety
• CV applications to support hazard warning
• Vehicle automation

Please, note that the above list should be considered as an initial list and other applications can be included by the FDOT in future efforts.

5.1.1 Outcome Performance Modification Parameters

Where applicable, the benefit parameters used in the original version of FITSEVAL are used as a starting point in this project. These parameters were updated in this document based on the following resources:

• A review of CV-based application benefits for arterials streets has been conducted, as part of an on-going research project conducted for the FDOT by the research team. The review conducted as part of that project (Project BDV29 977-41, entitled “Connected Vehicle to Vehicle-to-Infrastructure Support of Active Traffic Management”) provides additional important inputs regarding the benefits of the ITS applications.
• The benefit data reported in the United States Department of Transportation (USDOT) Joint Program Office (JPO) benefit database (USDOT, 2019).
• The benefit data utilized in the TOPS-BC tool developed by the FHWA (Sallman et al., 2013)
• The parameters reported as part of FDOT District 5 FITSEVAL Phase 2 Effort (FDOT, 2016)

Gaps in the available information was identified and additional review is conducted as part of this project with focus on AV applications since the impacts of the CV-based arterial applications has already been reviewed as part of the project mentioned above and AV applications.

The parameters needed to assess the impacts of TSM&O/ITS application on mobility and reliability measures are required to modify the values calculated for the base conditions with no ITS applications. These parameters are referred to as mobility modification factors (MMF) and reliability modification factors (RMF) and obtained based on the resources mentioned earlier. In general, these parameters can be classified into:

• Modification factors that are the proportion improvements in the mobility and reliability outcome measures. The impacts of ITS in this case are calculated as the multiplication of the factors and the values of performance measures calculated using the procedures discussed in Chapter 3 including using speed-flow relationships, highway capacity procedure, reliability estimation equations, real-world data, and possibly simulation modeling.
• Modification factors that are applied to the inputs of the analytical models that allow calculating the outcome measures rather than to the calculated measures themselves. Examples of these measures can be the reduction in incident duration, percentage capacity drop due to incidents and work zones, lane-hour lost due to incidents, and capacity increase due to automated vehicles. This type of factors is preferred, if information is available to support it.

With regard to safety, the crash modification factors (CMF) of ITS applications are also obtained based on the resources mentioned above. These factors multiply the crash frequency for the highway segment with the base conditions assuming no ITS to obtain the crash frequency with ITS. As described earlier, the crash frequency with no ITS can be calculated using based on real-world data, safety performance functions, or the look-up table. It should be noted that, depending on ITS applications, the CMF may be applicable to all crashes, crashes of specific type (rear-end, sideswipe, pedestrian, left-turn, etc.), severity (fatal, injury, or property damage only (PDO)), or specific conditions (e.g., under incident or rainy conditions). Thus, the crash frequency has to be calculated first for the affected crash category and the result is multiplied by the CMF to account for the ITS impacts.

The ITS impact modification factors discussed in this document and as implemented in the updated version of FITSEVAL should be considered as initial values and should be updated when additional information become available. An on-going FDOT research center project is expected to provide recommendations for mobility and crash modification factors for TSM&O/ITS. The ITS impact parameters reported in previous evaluation studies, the benefit data reported in the USDOT JPO benefit database, and the results of field deployments should be continuously monitored to determine the most appropriate factors. The users shall be able to change the default parameters to reflect their reviews, judgment, and local conditions. The default and user input values for the ITS impact parameters shall include minimum and maximum values to allow conducting sensitivity or risk analysis.

The modification factors of different ITS applications as recommended in different sources and the values recommended for use as default in the new version of FITSEVAL are presented in the individual ITS Application sections, later in this document. Please, note all default values can be overridden by the user if better information is available.

5.1.2 Cost Parameters

Cost estimation is another required component of benefit-cost analysis. The cost estimation must consider the number and types of equipment required for each type of evaluated ITS deployment. FITSEVAL includes initial cost, operation and maintenance cost, estimated interest rate, and equipment life-time. The cost information also includes low, high, and average values for each item.

The study team reviewed the following cost data sources:
• The cost data reported in the United States Department of Transportation (USDOT) Joint Program Office (JPO) benefit database (USDOT, 2019).
• The cost data utilized in the TOPS-BC tool developed by the FHWA (Sallman et al., 2013).
• The parameters reported as part of FDOT District 5 FITSEVAL Phase 2 Effort (FDOT, 2016).
• The CV deployment cost used in the Near-Term V2I Transition and Phasing Analysis Life Cycle Cost Model tool (USDOT, 2015).
• Other data sources

The cost values of different ITS applications as recommended in different sources are presented in the individual ITS Application sections in this document. It should be pointed out that there is a lot of uncertainty in the cost of emerging technologies like those associated with CV and automated vehicle (AV)-based applications. Thus, the provided values should be considered as a starting point and further information should be used if more accurate costs can be estimated.

5.1.3 Conversion to Dollar Values

An important component of benefit-cost analysis is to convert ITS impacts to dollar values. The original version of FITSEVAL has default parameters to convert the mobility, safety, emission, and fuel consumption to dollar values. The FDOT District 5 FITSEVAL effort recommended updates to these parameters. The transportation Benefit-Cost Analysis wiki (B-C Wiki) that is sponsored by the TRB Committee on Transportation Economics (http://bca.transportationeconomics.org/) presents a detailed set of recommended values.

In addition to travel time cost, measures of reliability or variability has been used some times as part of the benefit dollar values. The standard deviation of travel time and other measures such as the differences of percentiles. The difference between the 80th percentile and median is used in this study. Previous research has estimated the ratio of the dollar value of travel time reliability to the dollar value of travel time referred to as travel time reliability value ratio to be between 0.8 and 1.3 based on stated preference surveys (B-C wiki, 2019). However, the decision to include this measure in the benefit-cost evaluation is left to the analyst since there may be a concern about double counting the benefits if both the travel time and travel time reliability values are included in the analysis.

Table 5-1 shows the dollar values of mobility, reliability, and safety; recommended in different sources and the values recommended for use as defaults in the new version of FITSEVAL.

5.1.4 Considering Uncertainty

Benefit–cost analyses of ITS alternatives produce point estimates of the return on investment of ITS deployments. These analyses used default or user input values of the cost, benefit, and dollar values of the benefits. However, there is a great amount of uncertainty associated with these parameters. The values of the parameters as reported in previous evaluation studies vary widely. Decision makers may not be willing to accept an alternative that has an acceptable average or median benefit–cost ratio but has a 25% probability of having a low benefit–cost ratio or if there is a relatively high probability that the budget of the project will be high. The uncertainty is even higher when dealing with connected and automated vehicle technologies. To account for the uncertainty, two approaches can be used:

Sensitivity analyses: This type of analysis involves separately varying the individual values of key input parameters of the return-on-investment analyses. This approach, however, does not allow the analyst to identify confidence limits and probabilities for the results of the analysis. To apply this approach, a range is established for each input variable based on previous studies. The high, low, and most likely values are identified. The next step is to calculate the benefit–cost measures using the most likely values of all variables. Then, for each variable, the benefit–cost measures are calculated with the high and low values of the variable, while fixing the other variable values at the most likely values. This will allow the identification of the range of the benefit–cost measure and how sensitive is the measure to the value of each variable.

Risk analyses: Risk analyses have been used to account for uncertainty in return on investment by expressing the input parameters as probability distributions rather than as fixed values. Usually, Monte Carlo simulation procedure is used as part of the risk analysis to vary the input parameters and identify probability distributions for each resulting performance measure such as the benefit-cost ratio or net worth value. An issue with this approach is that the distributions is that the distributions of the variables themselves are uncertain. The lognormal distribution has

</tr>
</tbody>
</table>
been used in estimating the evaluation of the benefits and costs in the project decision-making process. In a previous study conducted by the FIU research team (Yang et al., 2007), a general procedure was used to perform risk analysis in the evaluation of ITS benefits and costs. The procedure utilized lognormal distribution as part of Monte Carlo simulation process to describe the random variations in the input parameter values. The parameters of the lognormal distributions were estimated based on the highest and lowest values of the benefits reported in the literature. The method used to estimate these parameters are estimated in that paper (Yang et al., 2007).

The method recommended for the updated version of FITSEVAL is based on the risk analysis method described in Yang et al. (2007) paper. The first version of FITSEVAL does not include this feature but this will be included in a future effort.

5.2 Adaptive Signal Control with and without CV Support

Adaptive Traffic Signal Control (ATSC) allows better control of the intersection allowing green time adjustment based on the arrival traffic pattern. Due to stochastic nature of traffic arrival, the green time needs to be adjusted from cycle to cycle. ATSC will be able to make this adjustment, providing improvement in system performance. ATSC is one of the focus area for FDOT Statewide Arterial Management Program (STAMP) and the FDOT Transportation System Management and Operations (TSM&O) program.

There are some limitations with existing ATSC systems. In addition to the additional needs for sensors, these systems utilize aggregate traffic data from point detectors such as volumes and occupancies. Existing adaptive systems and associated algorithms are still constrained by the low fidelity of data available from current point detection technologies. These constraints limit the system awareness of the state of the traffic, which reduces the performance of adaptive signal control. Thus additional benefits are expected to be realized due to the application of adaptive signal control system that is supported by CV technology.

The following is a brief description of the method used to estimate the benefits of ATSC.

**Mobility:** A MMF is selected for the reduction in travel time and multiplied by the travel time estimated based on flow-speed relationship, HCM-based method, simulation, or real-world data. The MMF utilized previously and used in the updated version of FITSEVAL are shown in Table 5-2. Please, note that it assumes that the ATSC systems will provide more improvements in understated conditions. Also, please note that it is assumed that the benefits of adaptive signal control increases linearly with the increase in the market penetration of CV, if CV-based information are used to improve the control system. The market penetration growth rate that is a user input determines the number of connected vehicles for each year in the future but a default growth rate is used in the tool based on Iqbal et al. (2018).

**Reliability:** The reliability is calculated utilizing SHRP 2 L03 data poor model. This is because the SHRP 2 L03 data poor model is a function of the recurring mean travel time that is estimated with and without ATSC when estimating the mobility impacts. Therefore, the L03 model allows direct estimation of the reliability impact of the ATSC.
Safety: 17% reduction in property damage only crashes based on a previous study as shown in Table 5-2. This benefit is assumed to increase linearly to 27%, as the market penetration of CV increases from 0% to 100%, if CV-based information is used to improve the control system.

5.3 Transit and Freight Signal Priority with and without CV Support

Transit Signal Priority (TSP) and Freight Signal Priority (FSP) uses technology to realize approaching high priority vehicles and alter signal timings to provide priority control to transit/freight vehicles. The priority provisions are classified into two categories: conditional and unconditional. To get conditional priority, when detected, the transit/freight vehicle must meet the specified conditions, such as the number of passengers, freight category, route schedule adherence, or the time since last priority is awarded. Utilized priority strategies include green extension, early green, and to lesser extents actuated transit phase, phase insertion, and phase rotation. The priority requests can be made at the central level through center-to-center communication such as between the traffic management center with the transit management center and/or the freight management center/Intermodal terminal. It can also be made using a distributed (local) priority architecture.

CV-equipped vehicles can be tracked at a relatively long distance upstream of the intersection. This allows downstream signals to recognize the need to provide the priority earlier than what can be done with existing distributed priority implementations. This allows the controller to better prepare for the priority such as serves the phases with non-priority calls to reduce the delays for the vehicles served by these faces. Another example of the benefits of CV-based priority application is that it allows transit vehicles making a left-turn that are blocked by either a short left-turn pocket or long queue for the through movement which blocks the access of the left-turning bus to the left-turn pocket. When such a condition is detected, the system grants priority for the through movement to clear the queue to allow the transit vehicle to access the left-turn pocket sooner and grant priority for the left-turn movement to reduce delay of the transit vehicle. In addition, on-board CV units can be used to inform priority vehicle drivers that their priority requests will be met. Another challenge that faces existing TSP implementations that is uncertainty of dwell time associated with nearside bus stops. The nearside stop issue can be addressed by including bus door open/close status in the priority request messages combined with location information on the nearside stop. The queue between the bus and the nearside stop can be also considered.

The following is a brief description of the method used to estimate the benefits of TSP and FSP.

**Mobility:** MMF of the impacts of signal priority on transit or fright vehicles is multiplied by the travel time estimated based on flow-speed relationship, HCM-based method, simulation, or real-time data. Additional delay is added to the cross street vehicles, as indicated in Table 5-4. The agency may decide not to implement priority on all intersections. In addition, the agency may decide to implement conditional priority (such as schedule adherence, number of bus passengers, type of freight shipment, and/or weight-to-power ratio of the truck). If the priority is conditional, the benefits are only calculated for the buses that meet the conditions (default 60%). Thus, the benefits will be calculated as follows:

\[
T_{\text{with-TSP}} = T_{\text{without-TSP}} \ast (1 - \% \text{reduction in priority vehicle TT} \ast \\
\% \text{vehicles that meet conditions} \ast \\
\% \text{percentage of intersections that can be equipped})
\] (5-1)
For TSP, the saving in travel time is converted to passenger hour saving per year based on the number of passengers per bus. For freight, the saving in travel time is converted to truck-hour savings per year and then converted to dollar values considering the higher values of truck delays.

**Reliability:** The reliability is calculated utilizing SHRP 2 L03 data poor model. This is because the SHRP 2 L03 data poor model is a function of the recurring mean travel time that is estimated with and without TSP when estimating the mobility impacts. Therefore, the L03 model allows direct estimation of the reliability impact of the TSP.

**Safety:** CMF is applied to transit PDO crashes based on a previous study, as shown in Table 5-4.

Table 5-5 shows the cost parameters of priority implementation in previous studies and what is utilized in the updated version of FITSEVAL.

5.4 Speed Adjustment to Support Arrival on Green

Green Light Optimal Speed Advisory (GLOSA) is a CV-based application that involves providing information and guidance to drivers as they approach traffic signals to allow them to adjust their speeds to reduce the probability of stopping at downstream intersection. The speeds are calculated based on the vehicle’s location and Signal Phase and Timing (SPaT) messages and communicated to the vehicle using dedicated short-range communication (DSRC) or cellular communications. A more advanced application, referred to as Glide Path, automatically adjusts the speeds of the vehicles to allow them to arrive on green. An extension of this application is to combine adaptive signal control with GLOSA optimize the signal control.

The following is a brief description of the method used to estimate the benefits of GLOSA and Glide Path

**Mobility:** The travel time of connected vehicles is multiplied by a MMF factor that reflect the impact of the specific application (GLOSA or Glide Path), as shown in Table 5-6. The market penetration growth rate that is a user input determines the number of connected vehicles for each year in the future. A default growth rate is included in the tool based on Iqbal et al. (2018).

**Reliability:** The reliability is calculated utilizing SHRP 2 L03 data poor model. This is because the SHRP 2 L03 data poor model is a function of the recurring mean travel time that is estimated with and without the GLOSA and Glide Path applications when estimating the mobility impacts. Therefore, the L03 model allows direct estimation of the reliability impact of the GLOSA and Glide Path.

**Safety:** It is assumed that the PDO of CV with this application is reduced by the same proportion of the improvement in mobility.

5.5 CV Application Support of Signalized Intersection Safety

CV-based applications have been proposed to provide solutions to address transportation safety concerns. A number of these applications have been suggested to support signalized intersection safety including Signalized Left Turn Assist (SLTA), Red Light Violation Warning (RLVW), and Pedestrian in Signalized Crosswalk Warning (PCW).

The benefits of these applications are calculated as follows:

**Mobility:** Some safety applications, particularly the non-CV solutions may have adverse impacts on mobility. For example, protecting a left turn to increase its safety will result in increase in intersection delay. This adverse impacts can be calculated based on HCM-based or simulation-based analysis.

**Reliability:** The reduction in crashes will increase the reliability of the traffic stream due to the reduction of non-recurrent delay. The SHRP 2 L03 model cannot account for this since it does not account for the reduction in non-recurrent delay. Thus, the SHRP 2 C11 model reliability model that estimate travel time reliability based on AADT and non-recurrent delay will be used. The non-recurrent delay in this model accounts for the reduction in the number of incidents due the safety applications.

**Safety:** The base number of crashes for the evaluated intersection without the application is calculated based on actual real-world data, utilizing the table look-up method, or the Florida SPF functions. CMF were estimated for CV-based solutions and non-CV based solutions to the safety issues based on a review of what is available in the literature. The base crash frequency is then multiplied by these CMF the predicted number of crashes with different safety applications. A summary of the identified CMF are presented in Table 5-8. Depending on the application, the modification factors may be only applied to specific types of crashes such as pedestrian or rear-end crashes or specific severity such as injury or PDO.

5.6 CV Application Support of Unsignalized Intersection Safety

There are non-CV applications that can be used to increase the safety of un-signalized intersection safety. For example, flashing beacons can be used to warn drivers of a stop sign ahead. Another example is the modification of unsignalized intersection to J-turn intersection to increase the intersection safety.

Reliability: The reduction in crashes will increase the reliability of the traffic stream due to the reduction of non-recurrent delay. The SHRP 2 L03 model cannot account for this since it does not account for the reduction in non-recurrent delay. Thus, the SHRP 2 C11 model reliability model that estimate travel time reliability based on AADT and non-recurrent delay will be used. The non-recurrent delay in this model accounts for the reduction in the number of incidents due the safety applications.

Safety: The introduction of CV technology can provide safety benefits for unsignalized intersections. Two such applications have been suggested: Stop Sign Violation Warning (SSVW), and Stop Sign Gap Assistance (SSGA). SSVW warns the vehicle driver if the vehicle is predicted to violate a stop sign. This application will reduce crashes with the cross-street traffic and may also reduce the number of rear-end. The SSGA provides advisory information to cross-street drivers at a stop-sign controlled intersection to support their gap selections at the intersection. To estimate the benefits, the base number of crashes without unsignalized intersection applications is calculated based on real-world data or utilizing the table lookup method or the Florida SPF curve. CMF, identified based on the literature, are then multiplied by the base number of crashes to predict the number of crashes with the unsignalized intersection applications. A summary of the identified CMF are presented in Table 5-10.

The cost parameters of the safety applications to unsignalized intersection are presented in Table 5-11.

5.7 Hazard Warning

Existing safety solutions that assist drivers along a roadway segment includes warning drivers of unsafe speeds/unsafe speeds on curves, warnings drivers of oversize vehicles, warning drivers of bad weather and pavement conditions, and railroad crossing warning. Different CV applications that assist driver on hazard warning are Reduced Speed Zone Warning (RSZW), Curve Speed Warning (CSW), Oversize Vehicle Warning (OVW), Spot Weather Information Warning (SWIW), and Railroad Crossing Violation Warning (RCVW).

Reliability: The reduction in crashes will increase the reliability of the traffic stream due to the reduction of non-recurrent delay. The SHRP 2 L03 model cannot account for this since it does not account for the reduction in non-recurrent delay. Thus, the SHRP 2 C11 model reliability model that estimate travel time reliability based on AADT and non-recurrent delay will be used. The non-recurrent delay in this model accounts for the reduction in the number of incidents due the safety applications.

Safety: The number of crashes without hazard warning is calculated based on real-world, utilizing the table lookup method or the Florida SPF functions. CMFs are then multiplied by these numbers to predict the number of crashes with hazard warning. The identified CMF for the hazard warning applications are shown in Table 5-12.

The cost parameters of the safety applications to unsignalized intersection are presented in Table 5-13.

5.8 Effect of Automation

Automated Vehicle (AV) will play an important role both for increasing mobility and safety of the roadway. The updated version of FITSEVAL also incorporates the effect of automation on roadway as part of FITSEVAL tool. The introduction of different levels of automation will allow the reduction of crashes and the severity of injuries and will improve mobility, reliability, and accessibility of the transportation systems. In this study, we have reviewed the reported mobility and safety impacts for these levels of automation that are capable to target different percentages of crash population depends on the level of automation or combined levels of automation.

A technical report (Smith et. al., 2015) published by the USDOT titled “Benefits Estimation Framework for Automated Vehicle Operations” summarized a list of the following autonomous vehicle applications as shown in Table 5-14.

**Table 5-14: List of Automated Vehicle Applications (Source: Smith et al. 2015)**

<table>
<thead>
<tr>

Reliability: The reduction in crashes will increase the reliability of the traffic stream due to the reduction of non-recurrent delay. The SHRP 2 L03 model cannot account for this since it does not account for the reduction in non-recurrent delay. Thus, the SHRP 2 C11 model reliability model that estimate travel time reliability based on AADT and non-recurrent delay will be used. The non-recurrent delay in this model accounts for the reduction in the number of incidents due the safety applications.

Safety: CMF was identified based on reviewing previous studies as shown in Table 5-15. Such CMF can be used to multiply the base crash frequency estimated based on the real-world, lookup table, or SPF functions. Cooperative automated vehicles will also impact on the roadway capacity. A summary of the capacity improvement with different autonomous vehicle application is provided in Table 5-16.

Table 5-16: Capacity Benefits of Vehicle Automation
5.9 FITSEVAL Update

The original version of FITSEVAL was produced utilizing the Script language of Cube. It works only as a processor to cube provided input and output files, in addition to analyst supplied parameters utilizing the user interface. The new version of FITSEVAL is a standalone desktop tool that reads files from multiple sources as long as it is provided in an acceptable format. The currently acceptable format are Cube files and Highway Capacity Software (HCS) file format. The source of the data can be any model or real-world data as long as it is converted to one of these two formats. The software itself is coded in the C# language. The user does not need to use the C# language to utilize the tool since it is compiled and used in an executable form. The final product is an executable file which could be run on any windows platform. Thus, the user only needs to interface with the tool through the graphical user interface (GUI), input files, and output files.

Figure 5-1 shows the assessment of the base condition mobility based on demand model outputs (FSUTMS model). The user has the option to utilize the travel time estimated by the demand model or to override the travel times utilizing previously calibrated travel time-volume/capacity equations that were found in this study to perform well compared to other equations. The volume and capacity used in these equation will be based on the demand model outputs. The individual link performance is presented in tabulator format at the lower half of the screen. The performance of the overall analyzed network is presented in the gauges at the upper half of the screen. The metrics estimated based on the demand model outputs are:

- Speed
- Excess delay
- Vehicle-mile traveled
- Vehicle-hour traveled
- Vehicle-hour delayed
- Vehicles per lane-mile
- Vehicle occupancy
- Percentage of Non-SOV
- Person-Trips
- Person-miles traveled
Figure 5-1: Mobility Performance Metric Estimation based on Demand Forecasting Models

Figure 5-2 shows the same type of assessment but based on the HCS outputs. Somewhat different metrics are calculated based on the outputs from the HCS model due to the availability of different types of information, as shown in Figure 5-2. The metrics estimated based on the demand model outputs are:

- Speed
- Excess delay
- Vehicle-mile traveled
- Vehicle-hour traveled
- Vehicle-hour delayed
- Vehicles per lane-mile
- Through Delay
- Stop rate
- Running Time

A powerful feature is that the user can put two or more different assessments side-by-side for comparison purpose. For example, in Figure 5-3, the mobility performance based on the HCS and that based on the demand model are compared. If the mobility assessment is also done based on real-world data, the comparison can also be made with this assessment. Figure 5-4 shows a comparison of the assessment of mobility with and without CV-based adaptive signal control. Figures 5-5 and 5-6 show the reliability estimation based on the demand model outputs and HCS, respectively. Figures 5-7 and 5-8 show the safety estimation based on the demand model outputs and HCS, respectively.
