211 Limited Access Facilities

211.1 General

This chapter includes criteria for limited access facilities (tolled and non-tolled), including:

1. Interstates
2. Freeways
3. Expressways
4. Interchange ramps servicing high speed limited access facilities
5. Collector-distributor roads (C/D) servicing high speed limited access facilities

Express lanes design is an iterative process best performed in a collaborative environment involving various disciplines e.g. express lanes planning, PD&E, construction, maintenance, traffic operations, transportation systems management and operations (TSM&O), and Turnpike toll operations. An explanation of the process and considerations is given in *The Express Lanes Handbook* Sections 6 and 8.

Many design criteria are related to design speed; e.g., vertical and horizontal geometry, sight distance. When the minimum design values are not met, an approved Design Exception or Design Variation is required. See *FDM 201.4* for information on Design Speed. See *FDM 122* for information on Design Exceptions and Design Variations.

The following manuals and documents provide additional information for the design of limited access facilities:

- **General Tolling Requirements (GTR)** - This document is used for design criteria and requirements for tolling on Turnpike and Non-Turnpike projects. This includes "open road" tolling facilities, express lanes (managed lanes, high occupancy tolling lanes, etc.) on new or existing corridors.
- **Turnpike Design Handbook (TDH)**
- **Express Lanes Handbook**
- **Traffic Engineering Manual (TEM)** - This manual is used to supplement the *Manual on Uniform Traffic Control Devices (MUTCD)*’s standards and guidelines with Florida specific signs and pavement markings used on the State Highway System by the Department’s Traffic Operations Offices.
Example roadway typical sections are included in the exhibits in *FDM 306*. Criteria regarding lanes, medians, and shoulders for bridges are illustrated in *FDM 260.1.1*. Subsequent sections of this chapter contain specific information and criteria regarding these and other typical section elements, as well as geometric features.

For interstate resurfacing projects, the standards used for horizontal alignment, vertical alignment, and widths of median, traveled way and shoulders may be the AASHTO interstate standards that were in effect at the time of original construction or inclusion into the interstate system.

Specific requirements for placement of the toll site infrastructure (e.g., tolling equipment structures (gantries), equipment buildings, utilities) is given in the *GTR*.

### 211.2 Travel Lanes and Auxiliary Lanes

Provide 12-foot travel lanes and auxiliary lanes on limited access facilities.

#### 211.2.1 Ramps

On tangent and large radii (500 ft. or greater) sections, provide a 15-foot traveled way for one-lane ramps and 24-foot traveled way for two-lane ramps.

Consider providing a greater lane width for one-lane ramps where accommodation of future resurfacing is a factor.

Ramp widths in other areas such as terminals are controlled by the curvature and the vehicle type selected as the design control. Minimum ramp widths for turning roadways are given in *Table 211.2.1*. Typical details for ramp terminals are provided in the *Standard Plans, Index 000-525*.

   (b) Case II - SU vehicles govern design, some consideration for semitailer combination trucks.
   
   (c) Case III – P vehicles govern design, some consideration for SU trucks.

(2) *AASHTO* adjustments do not apply.
211.2.2 Pavement Cross Slopes

For roadways, the maximum number of travel lanes with cross slope in one direction is three lanes except as shown in Figure 211.2.1, which prescribes standard pavement cross slopes. A Design Variation or a Design Exception is required when proposed pavement cross slopes do not meet the requirements shown in Figure 211.2.1.

The maximum algebraic difference in cross slope between adjacent through lanes is 0.04. The maximum algebraic difference in cross slope between a through lane and an auxiliary lane at a turning roadway terminal is given in Table 211.2.2.

Cross slopes on bridges are to be on a uniform, straight-line rate, typically 0.02 (See FDM 260.4). Use transitions to adjust for differences in cross slope between the approach roadway section and the required straight-line slope for bridge decks. Whenever possible the transition should be accomplished on the roadway section, outside the limits of the bridge and approach slabs. This will require detailing of the transition(s) in the roadway plans. Coordination between the Roadway, Drainage and Structures designers in the development of transitions is required to ensure compatibility and harmonizing at bridge approaches.
Figure 211.2.1  Standard Pavement Cross Slopes

All Travel Lanes One Direction

(1) These sections show only the standard slopes for adjoining travel lanes; they do not prescribe needed lanes, lane usage or typical section requirements other than lane slope.

(2) Maximum pavement cross slopes for on tangent sections are:
   (a) 0.03 for design speeds greater than 45 mph
   (b) 0.035 may only be used for 5-lanes sloped in one direction as shown above for all design speeds.

(3) The maximum change in cross slope between adjacent through lanes is 0.04.

(4) 4 or more lanes sloped in one direction (*) may be used with design speed 65 mph or less and longitudinal grades not exceeding 5%.

- **Algebraic Difference**
211.2.2.1 Existing Pavement Cross Slopes

Review the existing pavement and shoulder cross slopes for compliance with criteria. Field verify existing pavement and shoulder cross slopes by one of the following:

1. Full Digital Terrain Model for the roadway width – evaluate cross slope on tangent sections at 100-foot intervals.

2. Vehicle Mounted Scanner – prior to design, using the results of the scan, determine roadway limits where cross slope is potentially out of tolerance and request Digital Terrain Model of the roadway width for these limits. Evaluate cross slope on tangent sections at 100-foot intervals.

If cross slopes do not meet the values in Table 211.2.3, additional cross sections may be required by the designer to develop cross slope correction details and estimate material quantities. Resurfaced pavement and shoulder cross slopes should meet new construction criteria. When cross slope correction is not practical, documentation in the design file is required. If existing conditions are within the allowable range shown in Table 211.2.3, the term “Match Existing” may be used on the Typical Section(s) to indicate that the existing cross slope is to remain. Superelevation requirements are covered in FDM 211.8.

When cross slope correction is necessary, work closely with the District Pavement Design Engineer and the District Bituminous Engineer to determine the appropriate method of correction. Tabulate existing cross slopes in the plans at 100-foot intervals within the limits of cross slope correction. Include cross slope correction details showing the method of correction in the plans (see examples in FDM 306). Do not show cross slope correction details on the roadway cross sections. Base cross slope correction material quantities on the method of correction shown in cross slope correction details.
Table 211.2.3 Allowable Range for Existing Pavement Cross Slopes

<table>
<thead>
<tr>
<th>Facility or Feature</th>
<th>Standard (ft./ft.)</th>
<th>Allowable Range (ft./ft.)</th>

<td>0.020 - 0.080</td>
</tr>
<tr>
<td>Median (left) Shoulder</td>
<td>0.05</td>
<td>Adjacent Lane Cross Slope - 0.080</td>
</tr>
</tbody>
</table>

(1) Standard cross slope (0.02 or 0.03) as designated in Figure 211.2.1.

(2) The algebraic difference in cross slope between adjacent travel lanes must not exceed 0.04. The maximum algebraic difference in cross slope between a through lane and an auxiliary lane at a turning roadway terminal must meet Table 211.2.2.

(3) When existing shoulders are to remain, the algebraic difference between the shoulder slope and adjoining roadway pavement slope must be ≤ 0.07.

211.2.3 Hydroplaning Risk Analysis

The hydroplaning risk analysis predicts the water film thickness on the pavement being analyzed and the speed at which hydroplaning may occur. This information may support utilizing a non-compliant typical section when weighed against the cost of correcting pavement cross slope. Coordinate with the District Drainage Engineer to determine whether a hydroplaning analysis is needed.

Modification for Non-Conventional Projects:

Delete last sentence in above paragraph and see RFP for requirements.

When a hydroplaning risk analysis is performed, use the HP Program and the Design Guidance: Hydroplaning Risk Analysis. The Hydroplaning Tools can be downloaded under Design Aids at:

http://www.fdot.gov/roadway/Drainage/ManualsandHandbooks.shtm

211.2.4 Roadway Transitions

The minimum merging roadway transition length (L) is calculated as follows:
(1) Use \( L = WS \) for design speeds \( \geq 45 \text{ mph} \)
(2) Use \( L = WS^2/60 \) for design speeds \( \leq 40 \text{ mph} \)

Where: \( L = \) length of taper, feet
\( W = \) width of lateral transition, feet
\( S = \) design speed, mph

*Exhibits 210-1* through *210-6* illustrate standard roadway transitions. For conditions not addressed in these figures, use the following:

- Merging Taper = \( L \)
- Shifting Taper = \( L/2 \)
- Shoulder Taper = \( L/3 \)

Where an abrupt change in roadway typical (e.g., 4-lane section to a 6-lane section) a striped lane transition may be considered when all the following conditions are met:

- New pavement widths are not substantially greater than the joining pavement,
- Grade differentials are slight, and
- Future widening is expected.

### 211.2.5 Number of Lanes on the State Highway System

See *Section 335.02(3)* of the *Florida Statutes* for the number of lanes to be provided on the State Highway System. Nothing in this statute precludes a number of lanes in excess of ten lanes. The Department will determine the appropriate number of lanes based on traffic demand. Consideration will be given to availability of right of way and the capacity to accommodate other modes of transportation within existing rights of way.

*Topic No.: 525-030-020a Capacity Improvement Alternatives* is the Department policy to assist in the identification of the most appropriate option for widening projects on all limited access facilities on the State Highway System (SHS). This policy applies to the Interstate System and to Florida’s Turnpike Enterprise facilities.

### 211.3 Medians

Median width is the distance between the inside (median) edge of the travel lane of each roadway. Required median widths are given in *Table 211.3.1*. 
Median ditches must be designed to meet the following requirements:

- Have sufficient depth to provide positive drainage of the adjacent sub-grades. Typically this requires a median depth of at least one foot below the sub-grade shoulder point.

- Have recoverable side slopes within the clear zone in order to facilitate the recovery of errant vehicles. See *FDM 215* for additional information on roadside safety.

- Have sufficient longitudinal gradient and hydraulic capacity to ensure good drainage.

### Table 211.3.1 Minimum Median Widths

<table>
<thead>
<tr>
<th>Facility Type</th>
<th>Minimum Median Width (ft.)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interstate, Without Barrier</td>
<td>64</td>
</tr>
<tr>
<td>Freeway and Expressway, Without Barrier</td>
<td>Design Speed ≥ 60 mph</td>
</tr>
<tr>
<td>Freeway and Expressway, Without Barrier</td>
<td>Design Speed &lt; 60 mph</td>
</tr>
<tr>
<td>All, With Barrier</td>
<td>26</td>
</tr>
</tbody>
</table>

(1) For Interstate (without barrier), provide an 88-foot median width when future lanes are planned.

Facilities that have the ability to be expanded for additional capacity in the future will be designed to accommodate that future expansion. For example, a 4-lane high-speed facility that has the potential to expand to a 6-lane facility (without express lanes) may be designed with a 50-foot median with barrier (e.g. guardrail, high tension cable barrier) instead of the required 60-foot median. A 50-foot median will accommodate a future 2-foot concrete median barrier, two 12-foot travel lanes and two 12-foot shoulders.

### Modification for Non-Conventional Projects:

Delete note (1) from *Table 211.3.1* and delete the above paragraph and see RFP for requirements.

### 211.3.1 Bridge Median

See *FDM 260.5* for information on bridge medians.
211.3.2 Median Crossovers

This section addresses permanent median crossovers (i.e., median openings). The criteria in this section do not apply to contra-flow crossovers placed for facilitating hurricane evacuation, nor does it apply to temporary construction crossovers. For temporary construction crossovers, refer to Standard Plans, Indexes 102-630 and 102-631.

Permanent crossovers are necessary to avoid excessive travel distances for emergency vehicles, law enforcement vehicles, and maintenance vehicles. Provide median crossovers only when there is a documented request and need for such a feature; however, they are to be limited in number and strategically located. The District Design Engineer (DDE) and the District Traffic Operations Engineer (DTOE) jointly approve the location of median openings.

The following AASHTO Green Book crossover recommendations have been adopted by the Department as requirements for permanent crossovers:

1. Not spaced closer than 3 miles apart.
2. Located only in areas with above-minimum stopping sight distance and without superelevated curves.
3. Not located within 1,500 feet of the end of a speed-change taper (of a ramp or facility widening/narrowing) or any structure (bridge, overpassing facility or overhead sign).
4. Not located where the median width is less than 25 feet.

Crossover locations that do not meet the above criteria require approval by the State Roadway Design Engineer. Non-conforming crossovers on Interstate facilities require approval by the State Roadway Design Engineer and Federal Highway Administration (FHWA).

The following additional FDOT criteria are also requirements for permanent crossovers:

1. Not located within 1.5 miles of any interchange.
2. Not located where the median width is less than 40 feet.
3. Not located in urban areas
4. Where continuous median barrier is present, openings for crossovers should not be greater than 5 miles apart between Interchanges.
Typical layouts for the design of median crossovers are provided in Exhibits 211-1, 211-2, and 211-3. These typical layouts may not cover all situations, but are provided as a guide for developing site-specific designs. Designs should accommodate the types of emergency vehicles expected to use the crossover. Law enforcement vehicles and typical ambulance sized vehicles can usually be easily accommodated. The typical layouts illustrated in the exhibits accommodate a SU design vehicle. To the extent practical, designs should accommodate larger emergency response vehicles such as fire trucks. This may require obtaining information from local emergency responders on the size and configuration of vehicles used. Except where median widths are wider than normal, fire trucks and other larger vehicles will likely not be able to make U-turns without encroaching or crossing travel lanes. As a minimum, designs should provide for the necessary minimum radii and width to allow the largest design vehicle to enter the crossover and stop as close to perpendicular to traffic as practical. All designs should be tested by superimposing the turning path of the design vehicle to insure the crossover will operate as expected.

On Interstate facilities, the FHWA directs that median shoulders approaching the crossover utilize the standard shoulder width, or existing shoulder width. FHWA advocates that the safety benefits derived by making the crossovers appear less conspicuous outweigh the benefits obtained by providing paved shoulders to accommodate acceleration and deceleration lanes for emergency vehicles, law enforcement, or other authorized vehicles.

The profile of the crossover are to conform as close as practical with travel way shoulder slopes and median side slopes so that the crossover is inconspicuous as possible to traffic. The paved width of the crossover should not be any wider than that necessary to provide for the largest design vehicle. Shoulder width for the crossover should be 8 feet minimum. Side slopes of the crossover (parallel with the mainline travel way) are to be 1:10 or flatter. However, side slopes may be transitioned to match the slope of a pipe culvert safety end treatment where a culvert crossing underneath the crossover is necessary to provide for proper median drainage.

For each proposed location, determine drainage requirements and make appropriate provisions. The drainage culvert shown in the exhibits are for example only. Either a mitered end section (1:4) or preferably a u-endwall with grate (1:6) should be used for culverts parallel with the mainline. In some cases existing median ditches are shallow and there will be minimal clearances available for even small size culverts.

Provide a pavement design equivalent to a limited access shoulder pavement; i.e., 12 inch Stabilized Subgrade, Base Group 1, and 1.5 inch Structural Course.

A "No U-turn" sign (R3-4) with an "Official Use Only" plaque (FTP-65-06) is required for permanent crossovers. To improve nighttime visibility for approaching emergency
responders, install yellow RPMs on the outside yellow edge line in advance of the crossover using the following pattern and spacing:

1. Three spaced 4” apart at 1500 feet,
2. Two spaced 4” apart at 1000 feet, and
3. One at 500 feet in advance of the crossover.

**Florida Administrative Code, Rule 14-97, Section 14-97.003(3)** (Access Control Classification System and Access Management Standards) regulates the location of driveway connections and median openings in interchange areas on arterial roads. This standard should be applied in accordance with the District procedures for implementing the Rule, and should not be confused with minimum requirements for limited access right of way.

### 211.3.2.1 Existing Crossovers

On reconstruction and resurfacing projects, evaluate the location of existing crossovers for conformance to the above criteria. For those locations that do not meet the criterion in **FDM 211.3**, do one of the following:

1. Remove or relocate crossover as a part of the project
2. Crossover locations that do not meet the **AASHTO Green Book** criteria require approval by the State Roadway Design Engineer to remain. Non-conforming crossovers on Interstate facilities require approval by the State Roadway Design Engineer and Federal Highway Administration (FHWA) to remain.
3. Crossover locations that meet the **AASHTO Green Book** criteria, but do not meet additional FDOT criteria require approval by the District Design Engineer to remain.

**Modification for Non-Conventional Projects:**

Delete **FDM 211.3.2.1** and replace with the following:

### 211.3.2.1 Existing Crossovers

Evaluate the location of existing crossovers for conformance to the criteria in **FDM 211.3**. Remove existing crossovers that do not meet this criterion.
211.3.3 Express Lanes Separation

Express lanes are always separated from the general use lanes or general toll lanes. Median openings and crossovers are prohibited within express lanes.

There are four types of express lanes separation treatments:

1. Barrier separation; see Figure 211.3.1
2. Buffer separation with express lanes markers; see Figure 211.3.2
3. Wide buffer separation; see Figure 211.3.3
4. Grade separation; see Figure 211.3.4

The minimum standard buffer width for the buffer separation is 4 feet. Any variation from a 4-foot-buffer width must be approved by the District Design Engineer. Install express lane markers per the TEM, Section 4.2. Use barrier separation or grade separation when implementing a reversible express lane system.

**Modification for Non-Conventional Projects:**

Delete second sentence in above paragraph and see RFP for requirements.

The maximum spacing and placement of express lanes markers is provided in the TEM. If, based on operational and safety analysis, the EOR or the district wishes to increase the maximum allowable spacing, a Design Variation must be approved by the Chief Engineer.

When a wide buffer separation is selected the buffer may include a grassed median, or pavement with markings that is not more than one-lane wide. Refer to the Express Lanes Handbook for additional considerations for wide buffer separation.

** Modification for Non-Conventional Projects:**

Delete second sentence in the above paragraph and see RFP for requirements.

2. Minimum turning radius for SU vehicle shown, and were generated by AutoTURN.
3. For lane and median configurations other than the 6-lane, 40-foot median shown here, adjustments in turn radii or additional pavement may be required.

EXHIBIT 211-3
01/01/2018
211.4 Shoulders

Roadway shoulder width is measured from the edge of the traveled way to the shoulder break. A portion of the shoulder is required to be paved. Required shoulder widths and paved widths are given in Table 211.4.1.

Refer to FDM 260.3 for bridge shoulder widths.

See General Tolling Requirements (GTR) for required paved shoulder width at tolling locations.

211.4.1 Express Lanes Shoulders

The required width for express lanes shoulders depends on the type of separation between the express lanes and the general use lanes or general toll lanes. When retrofitting express lanes in constrained conditions, shoulder widths in Table 211.4.1 may not be achievable without a Design Variation or Design Exception. Consult the Highway Safety Manual on safety tradeoffs when narrowing shoulder widths.

Modification for Non-Conventional Projects:

Delete second and third sentences in above paragraph and see RFP for requirements.

**With shoulder gutter:**

(1) Ramp shoulder pavement less than 6 feet in width that adjoins shoulder gutter must match the type, depth, and cross slope of the ramp travel lane.

---

211- Limited Access Facilities
211.4.2 Shoulder Cross Slopes

The standard cross slope is 0.06 on the outside shoulder and 0.05 on the median (or left) side for all roadway and ramp sections. *Figure 211.4.1* illustrates shoulder cross slopes in relationship to roadway cross slopes for normal and superelevated sections. For 5-foot (or less) paved shoulders, see *Figure 211.4.2*. When the inside travel lane is sloping toward the median, the inside shoulder cross slope may be increased to 0.06.

For projects constructed with concrete pavement, the first one foot of the outside shoulder is cast with the outside travel lane and will have the same cross slope (and superelevation) as the outside lane. Superelevation of the shoulder pavement is to be rotated about the outside edge of the outside slab.
Figure 211.4.1  Shoulder Superelevation
211.4.3 Limits of Friction Course on Paved Shoulders

Extend the friction course 8 inches onto both the median and outside paved shoulders of roadways.

For locations where median barrier wall is continuous and shoulder slopes toward the travel lane, consider constructing the inside shoulder pavement flush with the friction course placed on the adjacent travel lane. This will address any concerns for trapping water on the shoulder as demonstrated in Figure 211.4.3.
211.4.4 Audible and Vibratory Treatment

Audible and vibratory treatments provide a lane departure warning. Include either ground-in rumble strips or profiled thermoplastic audible and vibratory treatment on LA Facilities.

211.4.4.1 Ground-in Rumble Strips

Use ground-in rumble strips on mainline flexible pavement shoulders in accordance with Standard Plans, Index 546-010. Use the skip array on both inside and outside shoulders. Use the continuous array in advance of bridge ends for a distance of 1,000 feet or back to the gore recovery area for mainline interchange bridges. Figure 211.4.4 provides guidance for placement of ground-in rumble strips.

Exclude ground-in rumble strips at the following locations:

1. On bridges, terminate at the approach slab joint.
2. On approach to mainline toll plazas, terminate at the end of the mainline normal section.
(3) On All Electronic Tolling (AET) facilities within the tolling area as defined in Appendix 17 of the General Tolling Requirements (GTR).

(4) On outside shoulders of entrance ramp terminals, terminate at the point of the physical gore and resume at the end of the acceleration lane taper.

(5) On outside shoulders of exit ramp terminals, terminate at the start of the deceleration lane taper, and resume at the point of the physical gore.

(6) On either side of median crossover openings, terminate within 400 feet.

211.4.4.2 Profiled Thermoplastic

Use profiled thermoplastic for inside and outside edge line pavement markings on roadways with rigid pavement shoulders.
Figure 211.4.4 Placement of Ground-in Rumble Strips
211.4.5 Emergency Refuge Areas

Consider including Emergency Refuge Areas (ERAs) in areas where additional shoulder widths are deemed necessary (e.g., law enforcement, vehicle refuge). Coordinate with Traffic Operations, Maintenance, and Law Enforcement to determine if ERAs would be appropriate for the roadway facility.

For express lanes projects, consider ERAs where deemed necessary in coordination with Traffic Engineering and Operations, Maintenance, Law Enforcement, and Toll Operations. For express lanes in constrained conditions, a staggered shoulder may be designed to allow storage of disabled or damaged vehicles.

Modification for Non-Conventional Projects:

Delete *FDM 211.4.5* and see RFP for requirements.

211.4.6 Emergency Shoulder Use (ESU)

ESU will be used on the median shoulder on 6 lane limited access evacuation routes and will be used on the outside shoulder on 4 lane limited access evacuation routes. Evacuation routes can be found at the following website:

http://www.fdot.gov/emergencymanagement/esu/

A minimum 10-foot shoulder must be maintained for ESU along these evacuation routes. In addition, the placement of barriers next to the shoulder used for ESU should be limited as much as possible. Shoulder widths for ESU that are less than the 10-foot minimum should be addressed by RRR projects.

See *FDM 240.1.1* for ESU requirements during construction.

211.4.7 Use of Curb

Type F Curb may be used in areas with design speeds 45 mph or less. Type E Curb may be used in areas with design speeds 55 mph or less. This applies to both median and outside shoulder locations. All curb is prohibited in areas with design speeds greater than 55 mph.
211.4.7.1 Existing Curb

There are infrequent sections of curbed roadways in combination with guardrail on Limited Access facilities. When there is no crash history associated with these applications, the curb may remain when approved by the District Design Engineer (DDE). Approval by DDE is documented through the development of the Typical Section Package.

211.5 Roadside Slopes

Side slopes within the clear zone are typically 1:6 or flatter. When site conditions require the use of steeper slopes, refer to new construction criteria included in *FDM 215*.

<table>

<tbody>
<tr>
<td>Delete <em>FDM 211.5</em> and see RFP for requirements.</td>
</tr>
</tbody>
</table>

211.6 Border Width

For new construction the required border width is 94-feet, which is measured from the outside edge of traveled way to the R/W line. This width may be reduced in the area of a crossroad terminal, as long as the design meets the requirements for clear zone, lateral offsets, drainage, and maintenance access.

Fencing, or in special cases, walls or barriers are to contain limited access facilities. These treatments are to be continuous and appropriate for each location. Treatment height and type may vary under special conditions. The treatment is typically placed at or near the limited access right of way line, but location may be adjusted based on site-specific conditions (e.g., ponds, trees, bridges). Placement information and additional data is provided in *Standard Plans, Indexes 550-001, 550-002*, and *550-004*.

<tr>
<td>Delete third sentence in above paragraph and see RFP for requirements.</td>
</tr>
</tbody>
</table>
211.6.1 Border Width on Reconstruction & Resurfacing Projects

For reconstruction and resurfacing projects where additional R/W will not be acquired, a Design Variation is not required when the following minimum border width is met:

(1) The border width accommodates:
   (a) Roadside design components such as signing, drainage features, guardrail, fencing and clear zone
   (b) The construction and maintenance of the facility
   (c) Permitted public utilities

(2) Along ramps and mainline lanes where roadside barriers are used and thus clear zone is not applicable, the minimum border width from the back of a barrier or retaining wall must be 10 feet if maintenance vehicles have sufficient access from public R/W that is contiguous and unimpeded to the facility.

(3) If the maintenance access is not continuous along a barrier or wall, and thus maintenance vehicles and equipment would need to turn around, then a sufficient turnaround area must be provided that is acceptable and approved by Maintenance.

(4) Maintenance accessibility includes the ability for equipment and vehicles to maneuver around obstacles including fences, lights, signs, side slopes and ponds.

211.7 Horizontal Alignment

The centerline (CL) or baseline (BL) of construction defines the horizontal alignment for roadway and bridge construction. The CL or BL construction is a series of tangents connected by horizontal curves established by the Engineer of Record (EOR). CL or BL construction is often the same alignment as the BL of survey.

Horizontal alignment should be consistent with the expected posted speed and with environmental, physical, and economic constraints. Design speed is the principal factor controlling horizontal alignment.

Avoid placing horizontal curves, points of intersection (PI) and superelevation transitions within the limits of a structure or approach slabs. Placement of stationing equations within the limits of a structure should be avoided on contract plans. Such equations unnecessarily increase the probability of error in both the design and construction phase.
211.7.1 Deflections in Alignment

The point where tangents intersect is known as the point of intersection (PI). Although the use of a PI with no horizontal curve is discouraged, there may be conditions where it is necessary. The maximum deflection along the mainline and ramps without a horizontal curve are as follows:

- Design speed ≤ 40 mph is 2°00'00".
- Design speed ≥ 45 mph is 0°45'00".

211.7.2 Horizontal Curves

A horizontal curve should not be introduced near the crest of a vertical curve. The combination of horizontal and vertical curves can greatly reduce sight distance; i.e., hide the horizontal curve from the approaching driver. The hazard can be avoided by having the horizontal curvature lead the vertical curvature; i.e., the horizontal curve is made longer than the vertical curve.

Flatter curvature with shorter tangents is preferable to sharp curves connected by long tangents; i.e., avoid using minimum horizontal curve lengths. Avoid long tangents followed by sharp curves.

Table 211.7.1 provides the desirable horizontal curve lengths to be used in establishing the horizontal alignment. Desirable curve lengths for interstate, freeways and expressways are based on 30-times the design speed (30V), where V = design speed in mph. Desired curve lengths for low-speed ramps are based on 15-times the design speed (15V), and high-speed ramps are based on 30V.
### Table 211.7.1 Length of Horizontal Curve

</tbody>
</table>

(1) Provide the desirable length; however, when desired length cannot be attained, provide the greatest length possible, but not less than the minimum.

### 211.8 Superelevation

The criteria contained in *FDM 210.9* is applicable for Interstates, Freeways, and Expressways. The RRR criteria contained in *FDM 210.9.2* applies to limited access resurfacing projects.

Superelevation rates of 0.10 maximum are required on high speed limited access facilities, except for the portion of a ramp that adjoins an arterial. For the portion of a ramp that adjoins to an arterial, match the superelevation rate of the arterial. The terminal and the area abutting the limited access facility is controlled by limited access criteria and must be designed for 0.10 maximum superelevation rate.
211.9 Vertical Alignment

The profile grade line defines the vertical alignment for roadway and bridge construction. The profile grade line is a series of tangents connected by vertical curves. For undivided highways the profile grade line is typically located at the horizontal centerline of the roadway. For divided highways a profile grade line should be established for each direction of travel.

Meeting vertical alignment criteria assures proper transitions, sight distances, and clearances.

See FDM 210.10.3 for vertical clearance requirements.

Minimum vertical clearances for bridges structures is given in FDM 260.6.

211.9.1 Grades

The slope or grade of each tangent is expressed in percent rise (+) or fall (-); e.g., +2.000% or -2.000%. The maximum grades that may be used in establishing the vertical alignment in given in Table 211.9.1.

<table>
<thead>
<tr>
<th>Facility Type</th>

<tr>
<td>Ramps</td>
<td>7</td>
</tr>
</tbody>
</table>

(1) Roadways located in rolling terrain may be 1% greater than value shown in the table. However, LA Facilities designed to 70 mph will be restricted to 3% maximum grade.

(2) For roadways with significant (10% or more) heavy truck traffic the maximum grade used should not exceed 4%.

(3) For resurfacing projects, when existing grades do not meet the above requirements but meet the standards in effect at the time of construction, the existing grade may remain.

(4) One-way descending grades on ramps may be 2% greater than values show, in special cases.
The point where tangents intersect is known as the vertical point of intersection (VPI). When two tangent grades intersect and no vertical curve is provided, the “kink” is known as the point of intersect (PI). The maximum change in grade (i.e., algebraic change) without a vertical curve is provided in Table 210.10.2.

211.9.2 Vertical Curves

A vertical curve must be provided when the change in grade of two intersecting tangent grades exceed the values shown in Table 210.10.2. A vertical curve is identified by a curve length (L) which is equal to the product of the K value (K) and the algebraic difference in grades (A).

Tables 211.9.2 and 211.9.3 contain vertical alignment criteria for Interstates, Freeways, Expressways, and ramps.

Length, \( L = KA \)
Where: \( K \) = Rate of vertical curvature (a.k.a. K value)
\( L \) = Length of vertical curve, (feet)
\( A \) = Algebraic difference in grades, (percent)

1. New construction K values are based on an eye height of 3.5 feet and an object height of 6 inches. Resurfacing K values are based on an eye height of 3.5 feet and an object height of 2 feet.
2. The minimum curve length must not be less than values shown in Table 211.9.3.
3. Vertical curves within a system interchange are to use K values based on the higher system.
4. Use interstate, freeway, or expressway K values on vertical curves located within the ramp terminal area. Ramp vertical curve K values are used for ramps outside of the ramp terminal area.

</table>
The geometric design developed for interstates, freeways, or expressways considers locations where decision sight distance is critical such as interchanges, toll plazas, lane drops, and express lanes ingress/egress locations. Decision sight distance requirements are in *AASHTO Green Book, Section 3.2.3*. If it is not practical to provide decision sight distance at these locations, or if relocation of the critical decision points is not feasible,
special attention will be given to the use of suitable traffic control devices for providing advance warning of the sub-standard condition.

Do not place express lane ingress or egress within the limits of a Design Variation or Design Exception processed for sight distance.

211.11 Structures

Refer to *FDM 260* for information on bridge structures.
211.12  Interchange and Ramp Spacing

Interchange spacing is measured along the freeway or interstate centerline between the centerlines of the crossroads. Refer to *FDM 201.3* for the minimum spacing between adjacent interchanges.

In urban areas, spacing less than 1 mile may be used with C-D roads or grade-separated (braided) ramps.

The spacing between interchanges may also be dependent on the ramp connection spacing. The minimum connection spacing between the gore noses of adjacent ramps is provided in *Figure 211.12.1*.

**Figure 211.12.1  Ramp Connection Spacing**

L = Minimum distance in feet from gore nose to gore nose.
A = Between two interchanges connected to a freeway: a system interchange[2] and a service interchange.[3]
B = Between two interchanges connected to a C-D road: a system interchange[2] and a service interchange.[3]
C = Between two interchanges connected to a freeway: both service interchanges.[3]
D = Between two interchanges connected to a C-D road: both service interchanges.[3]

**Notes:**

These values are based on operational experience, need for flexibility, and signing. Check them in accordance with Exhibit 1360-12 and the procedures outlined in the *Highway Capacity Manual*, and use the larger value.

[1] With justification, these values may be reduced for cloverleaf ramps.
211.12.1 Weaving Sections

Weaving sections are defined in *2011 AASHTO Green Book, Section 2.4.6.* When an entrance is followed by an exit and the exit is on the opposite side of the through traffic, the minimum distance between gore noses is governed by weaving considerations per the procedure outlined in the *Highway Capacity Manual (HCM)*. On-Off Weaving is illustrated in Figure 211.12.1. If the minimum distance cannot be provided, the weaving must be eliminated and positive separation (barrier) must be provided. For more information regarding barriers, refer to *FDM 215*. Consider a braided ramp configuration to effectively achieve the required weaving distance. Braided ramps are used on a limited basis because of the large cost associated with them. When combining general use lane or general toll lane exits and express lanes exits in a braided ramp configuration the express lanes exits merge on the right side of the general use lanes or general toll lanes.

211.12.2 Interchange Connections

When a series of interchanges are closely spaced, attention must be given to the uniformity of interchange patterns and to lane balance. Refer to the concepts discussed in the *2011 AASHTO Green Book, Section 10.9.5*. Auxiliary lanes may be required to conform to lane balance requirements.

Successive auxiliary lanes less than 1,500 feet apart are prohibited. Auxiliary lanes may continue through an interchange to avoid this condition.

211.13 Ramp Terminals

Taper type and parallel type ramp terminals can be used to enter and exit a limited access facility. Geometric configuration for the taper and parallel types are depicted in *Standard Plans Index 000-525*.

The taper type ramp terminal is not to be used where a minimum of 50 mph design speed cannot be maintained.

The parallel type entrance terminal should be used when a bridge is located within the merging lane and when turning roadway speed is less than 60% of thru roadway speed. The length of the acceleration lane is determined by *2011 AASHTO Green Book, Table 10-3*.

The parallel type exit terminal should be used when the exit is partially hidden over the crest of vertical curve and when turning roadway speed is less than 60% of the thru
roadway speed. The length of the deceleration lane is determined by 2011 AASHTO Green Book, Table 9-22.

The selection of either a parallel or taper type depends on the geometrics of the highway as well as the roadway that the ramp is connecting to. In cases that have limited sight distance and close connections to a signal controlled arterial, parallel type terminals should be used to allow for sufficient deceleration.

At entrance ramps on an ascending grade, the portion of the ramp intended for acceleration and the ramp terminal should closely parallel the through roadway profile to permit entering drivers to have a clear view of the through road ahead.

Design speed of entrance and exit ramps for limited access facilities should be gradually decreased from the mainline limited access design speed to the design speed of the ramp. The minimum speed used to design the first curve adjacent to the limited access highway is 20 mph below the design speed of the highway.

Figure 211.13.1 illustrates a basic configuration and terminology used when designing ramp terminals.

Figure 211.13.1 Ramp Gore

211.14 Express Lanes Access Points and Access Types

The design of express lanes access points is based on major origin and destination patterns, the location of toll points, and the location of existing interchanges with the general use or general toll lanes. Refer to Express Lanes Handbook for considerations when identifying location of express lanes access points.

An access point serves one of three uses:

(1) Point of entry to the express lanes

211- Limited Access Facilities
(2) Intermediate point of entry/ingress or exist/egress
(3) Termination of express lanes

When determining the point of entry and the termination of express lanes, consideration is given to future phased implementation plans for the corridor depicted in the ultimate express lanes diagram. Avoid temporary access points. Refer to Express Lanes Handbook.

Avoid locating an express lanes access point in the same weaving area as other highway weaving movements; interchange on-ramps, interchange off-ramps or auxiliary lanes. Access points are located to provide the required weave length between the express lanes and general use lanes or general toll lanes. If placed closer than the required minimum weave length, additional traffic control devices are added to prohibit vehicles from cutting across traffic to get into the express lane or get out to the interchange exit.

Traffic operational analyses must demonstrate that queuing from vehicles exiting the express lanes to the general use lanes or general toll lanes will not encroach on the express lanes.

Refer to Section 2.42 of the TEM for guidelines on express lanes entrance/ingress and exist/egress signs and signing sequence.

211.14.1 Express Lanes Access Types

Refer to Express Lanes Handbook for design considerations when selecting the access type. On Florida’s express lanes, the following types of access are used:

- Slip Ramps
- Weave Lanes
- Weave Zones
- Direct Connect

Slip ramps, weave lanes, and weave zones on the Interstate do not require an interchange access request. A weave lane or weave zone is used in constrained conditions for intermediate ingress and egress points and requires approval of the District Design Engineer.

Direct connect ramps (Express Exits) are used for system-to-system connection between express lanes facilities, toll facilities, major arterials, park-and-ride facilities, and transit facilities. Express Exits on the Interstate require an interchange access request.
Standard geometric details are shown in *Exhibits 211-4* through *211-7*. The associated signing and pavement marking requirements at ingress and egress locations are shown in *Exhibits 211-8* through *211-11*.

211.15 Limited Access Right of Way

The following criteria will be used in establishing limited access (LA) limits along crossroads at interchanges:

1. For rural interchanges, LA R/W will extend along the crossroad a minimum distance of 300 feet beyond the end of the acceleration or deceleration taper. Where no taper is used, the LA R/W will extend a minimum distance of 300 feet beyond the radius point of the return. LA R/W will end at that same station for both sides of the crossroad based on the greatest distance from the LA facility.

2. For interchanges in urban areas, the criteria given above will apply except that the LA R/W will end a minimum of 100 feet beyond the end of taper or the radius point of the return.

3. Extend LA R/W for queue spillback on the arterial within interchanges of arterials and LA facilities.

4. For unsymmetrical interchanges such as half-diamonds and partial clover leaves, the LA R/W along the crossroad on that side having no ramp will extend to a point opposite that point controlled by the ramp.

5. Extend LA R/W along crossroads overpassing LA facilities (no interchange) approximately 200 feet from the LA facility R/W line. This distance may be reduced or omitted if the crossroad profile provides adequate sight distance for existing or proposed driveways. The fence is generally tied into the crossroad structure end bent unless required along the crossroad.

Any reduction in the values shown above for LA R/W limits must be approved by FHWA for interstate projects and by the District Design Engineer for non-interstate facilities.

211.16 Maintenance Access

Accommodation of access for maintenance is integral to the roadway typical section on LA facilities. Specific requirements for the area immediately adjacent to toll sites is contained within the GTR. Requirements for access through various roadside safety devices is contained within FDM 215.

Along ramps and mainline lanes where roadside barriers are used, the minimum border width from the back of a barrier or retaining wall is 10 feet. Provide sufficient access from public R/W that is contiguous and unimpeded to the LA facility for maintenance vehicles.
If the maintenance access is not continuous along a barrier or wall, and thus maintenance vehicles and equipment would need to turn around, then a sufficient turnaround area must be provided that is acceptable and approved by the District Maintenance Engineer.

Maintenance accessibility includes the ability for equipment and vehicles to maneuver around obstacles including fences, lights, signs, side slopes, and ponds.
