

## 201 Design Controls

### 201.1 General

Designs for highway and bridge projects are based on established design controls for the various elements of the project such as width of roadway, side slopes, horizontal and vertical alignment, drainage considerations and intersecting roads. Selection of the appropriate criteria and standards is influenced by traffic volume and composition, desired levels of service, functional classification, terrain features, context classification, and environmental considerations.

The identification of applicable design controls is needed to achieve:

- (1) Optimum safety.
- (2) Desired capacity and Level of Service.
- (3) Design consistency.
- (4) Cost effective designs.

#### 201.1.1 Capacity and Level of Service

The AASHTO publication *A Policy on Geometric Design of Highways and Streets*, the Transportation Research Board *Highway Capacity Manual*, and FDOT's [Quality/Level of Service \(Q/LOS\) Handbook](#) provide detailed analysis and calculation procedures used in determining the number and configuration of lanes required and the resulting levels of service provided. As illustrated in those texts the following factors greatly influence capacity and Level of Service:

- Roadway gradients and roadside developments
- Number, spacing, and types of crossings and intersections
- Traffic volumes and composition
- Signalization progression and interconnectivity

Design of signalized intersections should ensure an adequate Level of Service through the design year of the facility, especially when right of way acquisition is being considered. The capacity of an at-grade arterial or collector is primarily controlled by its ability to move traffic through signalized intersections, rather than the mid-block through lane capacity.

Use the operational analysis methods in the Highway Capacity Manual for design of signalized intersections. Information or assumptions on basic intersection geometrics, lane utilization, and movement-specific traffic volumes are provided by the designer. The primary output of the operational analysis method is Level of Service and delay at a signalized intersection; however, this method can be used to determine geometric requirements, signal timing, or service flow volumes.

Signal timing is interactive with geometric design. Changes to geometrics, such as adding a turn lane, must consider changes to the signal timing simultaneously. Department-approved software, including the Highway Capacity Software, should be used to simulate the operation of independent or interconnected signals. Output from these programs can be used for the analysis and evaluation of proposed designs.

## 201.1.2 Design Consistency

Design consistency is achieved when the geometric features of the roadway are consistent with the operational characteristics expected by the driver. Design consistency alleviates driver uncertainty and inappropriate driver response. Following the criteria contained in this manual will assure design consistency; however, special attention should be given at locations where sudden changes in design speed, alignment or cross section occur, and in the development of intersection designs.

Roadways may traverse through a variety of context classifications. As the context changes, the design speed for the roadway will also change. Changes in design speed may also occur based on FDOT policy or to conform to operational or geometric conditions. Consistent signing and pavement marking designs in transition areas is an important aspect in meeting driver expectancy. See **FDM 201.4** for information on design speed.

Two examples of sudden change in cross section are where a narrow bridge exists and when the number of travel lanes increase or decrease. The FDOT [Standard Plans](#) provide guidance on accepted practices in these areas. Changes in the cross section may also occur when there is a change in the context classification.

Critical design elements that affect design consistency, driver expectancy, and vehicular operation include:

- Horizontal and vertical alignment
- Embankments, slopes, and guardrail applications
- Bridge width and roadway shoulders
- Pavement crown, cross slope, and superelevation

- Signing and delineation
- Placement of signal, lighting, and utility poles

## 201.2 Traffic and Design Year

To provide for an interconnected transportation system that insures the mobility of people and goods, designs should satisfy capacity needs at an acceptable level of service through the design year. Forecasted traffic demand and volume are used to establish the number of travel and turn lanes, turn lane storage, signal timing, and right of way requirements. Forecasted traffic should account for anticipated future land use development.

The design year is the year for which the proposed improvement is designed. The FDOT *Project Traffic Forecasting Handbook* states that the design year is usually 20 years from the Opening Year, but design period may range in years from the present to 20 years depending on the project type.

Design year period typically used on FDOT projects are as follows:

- 20 years for new construction and reconstruction projects
- 15 years for lighting projects
- 10 years for signalization projects
- 10 years for improvements included with RRR projects
- 0-10 years for safety and operational improvements

Traffic forecasting is also used in pavement design to determine the vehicular loadings on the pavement. The proposed pavement design must provide structural strength through the pavement's service life. On pavement rehabilitation, the service life is 8 - 20 years for projects without milling and 12 - 20 years for projects with milling. The FDOT [Pavement Design Manuals](#) provide guidance.

Traffic forecasts are developed during the Project Development and Environmental (PD&E) study of a project. A Project Traffic Analysis Report is generally required. When a PD&E study is not conducted, traffic forecasts must be prepared early in the design phase. Project traffic used for design must be attested to by completing *Form 130b*, located in *FDM 103*.

Traffic data used for design includes:

Modification for Non-Conventional Projects:

Delete the previous sentence and replace with the following:

See RFP for the following traffic information:

- (1) AADT for the current year, opening year and design year.
- (2) Existing hourly traffic volumes over minimum of 24-hour period, including peak hour turning movements and pedestrian counts.
- (3) Directional distribution factor (D).
- (4) Standard K factor (K).
- (5) Truck factors (T) for daily and peak hour.
- (6) Design speed and proposed posted speed.
- (7) Design vehicle for geometric design.
- (8) Peak turning movements at signalized and problem intersections and major traffic generators.
- (9) Movements for future traffic generators that are scheduled during the service life should be considered.

### **201.3 Access Management**

Regulation of access is necessary to preserve the functional integrity of the State Highway System and to promote the safe and efficient movement of people and goods within the state. Under **Florida Statutes 335.18**, the Legislature authorized FDOT to develop rules to administer the "State Highway System Access Management Act". These are **Rule 14-96** and **Rule 14-97**; see **Tables 201.3.1, 201.3.2** and **201.3.3**. Designs are to comply with the statute, the rules, adopted procedures and directives, and the district program.

**Table 201.3.1 Rule 14-97 - Freeway Interchange Spacing**

Access Class	Area Type	Segment Location	Interchange Spacing (miles)
1	Area Type 1	CBD & CBD Fringe For Cities In Urbanized Areas	1.0
	Area Type 2	Existing Urbanized Areas Other Than Area Type 1	2.0
	Area Type 3	Transitioning Urbanized Areas, and Urban Areas Other Than Area Type 1 or 2	3.0
	Area Type 4	Rural Areas	6.0

**Table 201.3.2 Rule 14-97 - Arterial Access Classifications & Standards**

Access Class	Median Type	Connection Spacing (feet)		Median Opening Spacing (feet)		Signal Spacing (feet)
		>45 mph	≤45 mph	Directional	Full	
2	Restrictive with Service Roads	1320	660	1320	2640	2640
3	Restrictive	660	440	1320	2640	2640
4	Non-Restrictive	660	440			2640
5	Restrictive	440	245	660	2640 >45 mph 1320 ≤ 45 mph	
6	Non-Restrictive	440	245			1320
7	Both Median Types	125		330	660	1320

**Notes:**

1. "Restrictive" physically prevent vehicle crossing.
2. "Non-Restrictive" allow turns across at any point.
3. Speeds shown in this table are posted speeds.

**Connection Spacing Near Interchange Ramps:**

Connections and median openings located within 1,320 feet of interchange ramps require the following spacing (measured from the ramp furthest from the interchange):

- 440 feet ≤ 45 mph
- 660 feet > 45 mph
- 1,320 feet on Access Class 2 Facilities > 45 mph

**Table 201.3.3 Rule 14-97 - Interim Access Management Standards**

Posted Speed (mph)	Connection Spacing (feet)	Median Opening Spacing (feet)		Signal Spacing (feet)
		Directional	Full	
35 mph or less	245	660	1320	1320
36 - 45 mph	440	660	1320	1320
Over 45 mph	660	1320	2640	1320

In addition, FDOT adopted the ***Median Opening and Access Management Decision Process (Topic No. 625-010-021)***, which further defines the principles and processes for FDOT to implement the Access Management Statute and Rules.

Each district has established an Access Management Review Committee to guide actions in access management and median decisions through all FDOT's processes. Various district offices are responsible for driveway permit connections and administering other parts of the program.

Each roadway on the State Highway System is assigned an access classification which determines what roadway features and access connection modifications are appropriate to adhere to the program.

During the PD&E phase, a conceptual access management plan is prepared for the preferred alternative. Access management issues are addressed in the Preliminary Engineering Report. Designs are to implement access management decisions and commitments made during the PD&E phase.

For projects that did not go through a PD&E phase, access connections within the project limits are to be evaluated for compliance with the assigned access classification. Driveways, signal, and median opening spacing should be considered in the analysis of safety and operational problems. Modifications or closures to access may be the solution in certain cases.

**Rule 14-97.003(3)(b)** gives FDOT the authority to alter, relocate or replace connections in order to meet current FDOT standards.

**Rule 14-96.011** allows FDOT to revoke a permit "...if the connection causes a safety or operational problem on the State Highway System substantiated by an engineering study...".

**Rule 14-97.003(3)(b)** provides guidance on the treatment of existing features in the highway improvement process:

*“Existing lawful connections, median openings, and signals are not required to meet the access management standards. Existing access management features will generally be allowed to remain in place, but shall be brought into conformance with access management standards when significant change occurs or as changes to the roadway design allow.”*

Where revisions are necessary due to operational or safety problems, it may not be possible to upgrade a median opening or driveway connection to the current standards because of existing conditions or constraints. In these cases, provide the best solution, based on good engineering practice.

**Median Opening and Access Management Decision Process (Topic No. 625-010-021)** requires the following:

- (1) Any significant change to driveway access will be shown in the plans or the driveway will be replaced in the same location, width and configuration (number of lanes).
- (2) Access design and impacts to a right of way acquisition parcel should be determined prior to the right of way phase.
- (3) Changes to access details or decisions must be coordinated with District Right of Way and General Counsel’s offices in addition to the Access Management Review Committee.

Properties that abut a roadway on the State Highway System has a right to reasonable access to the roadway. A means of reasonable access cannot be denied except on the basis of safety and operational concerns as provided in **Section 335.184, Florida Statutes**. Nothing in **Section 335.184** limits FDOT's authority to restrict the operational characteristics of a particular means of access. Service roads provide reasonable access.

It should be noted that if there are any conflicts between this manual and the statute and rules, the statute and rules will govern.

Modification for Non-Conventional Projects:
See RFP for special requirements.

## 201.4 Design Speed

Design speed is a principal design control that regulates the selection of many of the project standards and criteria used for design. The selection of an appropriate design speed must consider many factors. The AASHTO publication, ***A Policy on Geometric Design of Highways and Streets***, has a thorough discussion on design speed.

There are three categories of design speed:

**High Speed:** Design Speeds 50 mph and greater.

**Low Speed:** Design Speeds of 45 mph and less.

**Very Low Speed:** Design Speeds 35 mph and less.

### 201.4.1 Design Speed Selection

Design speed should be selected early in the design process. Select a context-appropriate design speed to attain a desired degree of safety, mobility, and efficiency. Select design speeds in increments of 5 mph.

The District Design Engineer (DDE) and the District Traffic Operations Engineer (DTOE) jointly approve the selected design and posted speeds. This approval is a declaration that the posted speed will not exceed the selected design speed. This is to be documented on the Typical Section Package as described in ***FDM 120.2.3***.

**Table 201.4.1** provides an allowable range of mainline design speeds on the State Highway System. **Table 201.4.2** provides the minimum design speeds allowed on ramps.

Modification for Non-Conventional Projects:
See RFP for design speed.

**Table 201.4.1 Design Speed**

<b>Limited Access Facilities (Interstates, Freeways, and Expressways)</b>		
<b>Area</b>	<b>Allowable Range (mph)</b>	<b>SIS Minimum (mph)</b>
<b>Rural and Urban</b>	70	70
<b>Urbanized</b>	50-70	60
<b>Arterials and Collectors</b>		
<b>Context Classification</b>	<b>Allowable Range (mph)</b>	<b>SIS Minimum (mph)</b>
<b>C1 Natural</b>	55-70	65
<b>C2 Rural</b>	55-70	65
<b>C2T Rural Town</b>	25-45	40
<b>C3 Suburban</b>	35-55	50
<b>C4 Urban General</b>	30-45	45
<b>C5 Urban Center</b>	25-35	35
<b>C6 Urban Core</b>	25-30	30
<b>Notes:</b>		
(1) SIS Minimum Design Speed may be reduced to 35 mph for C2T Context Classification when appropriate design elements are included to support the 35 mph speed, such as on-street parking. (2) SIS Minimum Design Speed may be reduced to 45 mph for curbed roadways within C3 Context Classification. (3) For SIS facilities on the State Highway System, a selected design speed less than the SIS Minimum Design Speed requires a Design Variation as outlined in <b>SIS Procedure (Topic No. 525-030-260)</b> . (4) For SIS facilities not on the State Highway System, a selected design speed less than the SIS Minimum Design Speed may be approved by the District Design Engineer following a review by the District Planning (Intermodal Systems Development) Manager.		

**Table 201.4.2 Ramp Design Speeds**

<b>Ramp Connection Type</b>	<b>Minimum Design Speed (mph)</b>
<b>Loops and Semi-Direct</b>	30
<b>Outer Cloverleaf</b>	35
<b>Intermediate Portions of Long Ramps</b>	40
<b>Direct Connection</b>	50
<b><u>Express Lane Direct Connections:</u></b> <p>(1) Design speeds higher than the minimum shown above should be used when practical. A design speed of 60 mph is desirable.</p> <p>(2) Design Variations for Design Speed will not be approved for Express Lane Direct Connections with a design speed below 40 mph.</p>	

### 201.4.1.1 Collector-Distributor Roads

The design speed for collector-distributor roads must not be less than 10 mph below the design speed of the primary facility when direct ingress or egress to the Limited Access facility is provided.

### 201.4.1.2 Express Lanes

Express lanes design speed will be the same design speed as the adjacent general use lanes or general toll lanes in roadways that have buffer and wide buffer separation. In cases of barrier and grade separation the design speed can be equal to or greater than that of the adjacent general use lanes or general toll lanes, but never less than the general use lanes or general toll lanes. Minimum ramp design speeds for Express Lanes ramps are included in **Table 201.4.2**.

### 201.4.2 Post-Construction Speed Study

The District Traffic Operations Engineer (DTOE) typically conducts a speed investigation within one year after a new construction or reconstruction project is completed. A change in posted speed limit may be proposed based on engineering and traffic investigations described in the Department's **Manual on Speed Zoning for Highways, Roads and Streets in Florida** (a.k.a. [Speed Zoning Manual](#)).

When a speed study indicates that a higher posted speed is warranted, a modification of posted speed limit may be made under the authority of the District Traffic Operations Engineer (per the Traffic Regulation Approval Process, [FDOT Procedure No. 750-010-011](#)).

To assign a posted speed higher than the design speed, the DTOE, working with the District Design Engineer (DDE) must process a Design Exception or Design Variation for each design element that does not meet the criteria for the higher speed.

Further explanation on how posted speed limits are developed can also be found on the State Traffic Operations web page:

<http://www.fdot.gov/traffic/FAQs/SpeedLimitFAQ.shtm>

### 201.4.3 RRR Projects

The design speed used for a RRR project is the design speed used in the original design of the highway.

When the posted speed is greater than the design speed used in the original design of the highway:

- (1) Process a Design Variation or Design Exception for each design element that does not meet the criteria for the higher posted speed. Refer to Design Variations and Design Exceptions that were processed when the higher posted speed was implemented.
- (2) Use criteria based on the posted speed:
  - (a) when correcting a specific highway feature that has a significant crash history
  - (b) for any new highway feature
- (3) For replacement of highway features, use criteria based on the posted speed to the greatest extent possible, but not less than the design speed.

The typical section package must reflect the design speed used in the original design of the highway and the current posted speed. Also list the required Design Variations and Design Exceptions in the typical section package. See **FDM 120.2.3.3**, Typical Section Sheet.

A Design Variation is not required when the design speed or posted speed is not within the allowable range shown in **Table 201.4.1**. When posted speed exceeds the allowable range, roadway elements that encourage lower operating speeds should be included with the project. See **FDM 202** for examples of roadway elements that encourage lower operating speeds.

### 201.5 Design Vehicle

The Design Vehicle is the largest vehicle that is accommodated without encroachment on to curbs (when present) or into adjacent travel lanes. The type of Design Vehicle is influenced by the functional and context classification of a roadway, the role of the roadway in the network, and the land uses served.

The selected Design Vehicle affects:

- Horizontal and vertical alignments

- Lane widths and lane assignments
- Roundabout inscribed circle diameter
- Intersection turning radii and sight distance
- Auxiliary lane storage length, and acceleration and deceleration lengths

When considering dual left turn or right turn lanes, the Design Vehicle should generally be considered as turning simultaneously with a passenger car.

**AASHTO's A Policy on Geometric Design of Highways and Streets** provides general guidance on the selection of a design vehicle. **AASHTO** also provides the dimensions and turning characteristics for a variety of standard design vehicles; e.g., P, SU, WB-40, WB-62.

**Florida Statutes** allow truck-trailer combinations that are similar to the AASHTO WB-62 Interstate Semitrailer with some slight modifications. This modified WB-62 design vehicle is defined as the Florida Interstate Semitrailer (WB-62FL) and is often used as the design vehicle on the SHS. In addition, the Florida's Turnpike and other truck routes allow tandem tractor trailers. Use the AASHTO WB-109D as the design vehicle for tandem truck routes.

Modification for Non-Conventional Projects:
See RFP for design vehicle requirements.

### 201.5.1 Control Vehicle

The Control Vehicle is one that is infrequent and is accommodated by allowing:

- Encroachment into opposing lanes if no raised median is present
- Minor encroachment on to curbs and areas within the curb return if no critical infrastructure such as traffic signal poles are present.

Control Vehicles may be appropriate at intersections for curbed roadways within C4, C5 and C6 context classifications. When considering U-turns, the Control Vehicle may be used as the Design Vehicle.

## 201.5.2 WB-62FL

When designing for a WB-62FL at intersections, the design elements (e.g., control radii, return radii) can be based on the criteria tables and figures in **AASHTO** for a WB-62. In addition, when designing features for complex or constrained intersections (e.g., roundabouts, multi-lane turns, directional median openings, ramps) the geometric design elements should be checked against the turning movement of a WB-62FL. The Florida Interstate Semitrailer WB-62FL is illustrated in **Figure 201.5.1**.

**Figure 201.5.1 WB-62FL**

<i>WB-62FL</i>		<i>feet</i>	
<i>Tractor Width :</i>	<i>8.00</i>	<i>Lock to Lock Time :</i>	<i>6.00 seconds</i>
<i>Trailer Width :</i>	<i>8.50</i>	<i>Steering Angle :</i>	<i>28.40 degrees</i>
<i>Tractor Track :</i>	<i>8.00</i>	<i>Articulating Angle :</i>	<i>70.00 degrees</i>
<i>Trailer Track :</i>	<i>8.50</i>
