Introduction

This report documents Florida's annual Statewide Seat Belt Use Survey. The survey was conducted in April and again in June of 2014 by Preusser Research Group, Inc. (PRG), under the direction of the Florida Department of Transportation, and under contract with Tallahassee Community College.

The Florida Department of Transportation (FDOT) is responsible for the State of Florida's Highway Safety Program. Occupant protection is among several significant program areas for which FDOT is responsible. A portion of FDOT's occupant protection program funding comes from the Federal Government, which requires administration of a statewide survey of belt use that must adhere to Federal Register Guidelines. Florida's first statewide survey certified under Federal Register Guidelines was completed in 1999. Surveys adhering to Federal Register Guidelines have been completed every year since. The survey first and foremost covered by this report was conducted in June 2014, and it succeeds in providing an accurate and reliable estimate of seat belt use in Florida, at a specific point in time, and is comparable to the first estimate accredited by National Highway Traffic Safety Administration (NHTSA) in 1999 and all statewide surveys conducted thereafter.

In spring of 2006, FDOT contracted with PRG to redesign the statewide survey, conduct observations, and develop an analysis methodology to determine a statewide seat belt use rate for the State of Florida for year 2006. Florida had an approved sampling plan in place since 1999, based on 351 sites across 13 counties. That plan was based on earlier population figures and needed updating. Rather than simply redraw the road sample, a modified design was developed using a new sample of counties and a smaller number of sites. The smaller number of sites in the 2006 design (151 versus 351) still provided an overall belt use estimate with much tighter variability than specified in NHTSA's 1998 TEA 21 Sample Design requirements, reducing costs to the State and NHTSA and still meeting all Federal Register requirements.

The design developed by PRG in 2006 was also used for conducting statewide surveys in 2007, 2008, 2009, 2010, 2011, and 2012 all for pre and post Click It or Ticket (CIOT) measurements. The State of Florida passed a primary enforcement seat belt bill (SB 344) on April 29, 2009, and the Governor signed that bill into law on May 6, 2009, with an effective date of June 30, 2009. The new law created an uninterrupted change from secondary enforcement of seat belt violations to primary enforcement. As a result, PRG utilized the design yet again in 2009 for a post-primary law change measurement in July.

In 2011, FDOT once again contracted with PRG, this time to redesign the statewide survey in order to meet new NHTSA design requirements for 2012.² The resulting design was built upon our earlier design. In the period 2005 – 2009, Florida had a total of 9,348 passenger vehicle

² National Highway Traffic Safety Administration. (2011) Uniform Criteria for State Observational Surveys of Seat Belt Use. 23 CFR Part 1340, Docket No. NHTSA-2010-0002, RIN 2127-AK41, Federal Register Vol. 76 No. 63, April 1, 2011, Rules and Regulations, pp. 18042 – 18059.

occupant fatalities, on a steadily downward trend, from 2,207 in 2005 to just 1,515 in 2009. Florida has a total of 67 counties. The 35 counties with the greatest numbers of these fatalities account for 85.4 percent of the passenger vehicle occupant fatalities. We utilized 15 of those counties, a number consistent with NHTSA's (1998) sampling recommendations and 3 more than in the previous design.

The State of Florida provided a database with all national, State, and major city and county road segments, by county. This database was exhaustive for all roadways that are Collectors or larger and was used for segment selections for those roadway strata. Florida also provided a complete census of local roadways for each of the 15 counties selected for the design, and those databases were used to select local road segments. All of the databases include segment identifiers, length, and traffic volume values (AADT and DVMT) for each segment. Segments are also classified by road function type and urban/rural location. This allowed development of road type strata.

The result is that all necessary information was provided for developing a sampling plan according to NHTSA guidelines. We selected 165 observation sites, 11 from each county, distributed across 5 roadway functional categories, or strata.

In order to assess the equivalence of the sampling design to the current plan, Florida measured belt use twice in June 2011, once following the previous plan and once following an example of what ultimately became the proposed plan. By comparing the results of the two plans, we were able to test for any systematic change in belt use figures due to the new observation plan. Ultimately, we measured a weighted use rate of 87.4 percent using the estimate plan; a result 0.7 percentage points below, but not statistically significantly different than, the 2011 reported rate of 88.1 percent utilizing the previous design.

Once the redesign plan was approved by NHTSA, PRG implemented the new survey in both April and June of 2012 to help verify CIOT program effects as well as determine a seat belt use rate for Florida under the revised model. This design was utilized again twice in 2013 for the same purpose. In 2014, two more survey replications were administered, one each for April and June. The results that follow primarily reflect the latter measurement; however, a summary section of select pre-post CIOT comparisons is provided as well. More information on the current design and sampling plan can be found in Appendix B.

Methodology

Site Selection

Prior to initial 2012 data collection, specific locations for data observations were tentatively selected based on visits to the locations, maps, and/or on-line road level images. The direction of travel observed was randomly determined for each segment/site. During the course of 2012 collection, final locations were determined and specific site location maps were drawn for ease in replication for subsequent surveys, including both 2014 measurements. The segments ultimately used for the 2012 and 2013 implementations of the survey were used again for 2014, with the exception of one replacement, and all are listed in Appendix E.

Sites were selected for observer and traffic safety, and where the observer appeared to have a clear view of the vehicles to be coded. Where possible, sites were selected where traffic naturally slows, though our highly trained observers are capable of making accurate seat belt use observations for moving traffic. In cases where specific site locations proved unusable or inferior, observers were able to choose other locations within the road segment where they can more effectively observe the same traffic stream. Were that not possible, observers could choose the next available segment of the same roadway type from a list of pre-selected alternates.

Data Collection

Observers

Observers were hired and trained exclusively by PRG. Most have conducted seat belt observations for us in previous surveys, and all were trained to the specific requirements of Florida belt use observation. Prior to any data collection, we reviewed the procedures with the observers in a training session which includes street-side practice. Additionally, observers were trained how to handle themselves in conditions, such as bad weather or temporary traffic impediments, which can require observation rescheduling and what to do to reschedule sites. They were also trained in how to substitute alternate sites should a primary site be completely unusable during the schedule period. Nine observers operated individually and three quality control monitors were utilized.

Scheduling

Observations were conducted on all days of the week during daylight hours between 7:00 a.m. and 6:00 p.m. In developing the schedules for the 2012 redesign, clusters of three to six sites were scheduled for one observer on any day, depending on how close the sites were and how difficult travel between sites was expected to be. First preference was for all sites in a county to make up their own two or three clusters. Road segments from the same stratum were distributed across clusters. For each county, the days of observation for the clusters were selected to balance observations across weekend and weekday days, with two-cluster counties including one weekend and two weekday days. Within these constraints, actual day of week assignments were randomly determined.

The first site in a cluster to be observed on the scheduled day was randomly selected and the additional sites were assigned in an order which provided balance by type of site and time of day while minimizing travel distance and time. For each site, the schedule specified time of day, day of week, roadway to observe, and direction of traffic to observe. Depending on the number of sites in a cluster, the time from 7 a.m. to 6 p.m. was divided into nearly equal-length time periods. For example, for five-site days, time of day was specified as one of five time periods, such as 7:00 – 9:00 a.m., 9:00 – 11:00 a.m., 11:00 a.m. – 2:00 p.m., 2:00 – 4:00 p.m., and 4:00 – 6:00 p.m. Also, for six-site days, time of day was specified as one of six time periods, such as 7 – 8:45 a.m., 8:45 – 10:30 a.m., 10:30 a.m. – 12:15 p.m., 12:15 – 2:30 p.m., 2:30 – 4:15 p.m., and 4:15 – 6:00 p.m. Fewer sites in the cluster generally result in more time in each period. Exact timing of the periods was subject to adjustment, but ultimately resulted in approximately equal numbers of sites being observed throughout the 7 a.m. – 6 p.m. time frame. The surveys in 2014 followed the final 2012 schedule. In all cases, the period of actual seat belt use observation lasted exactly one hour and was required to take place within the broader allowable time period.

Observation Site Details

Because of the extent of data to observe on each vehicle (see below), we gave preference to observation points where traffic appeared to naturally slow or stop. For street locations, and assuming they represent segments with generally equivalent traffic along the entire segment, we sought out suitable observation points toward the middle of the segments but accepted any location along the segment. Preferred locations are those that are near intersections which may cause vehicles to slow, increasing the time for observation and improving data completeness and accuracy. For limited access highway segments, we captured traffic at or near exit ramps where traffic will be slow enough to allow reliable and accurate observations to be made.

Collection Procedures

Data collection was done according to the instructions in Appendix C. All passenger vehicles less than 10,000 lbs GVWR are eligible to be observed. Survey information was recorded on an observation data collection form (Appendix D). The form is designed so that pertinent site information can be documented, including county name, city/town/area identifier, exact roadway location, date, day of week, time, weather condition, and direction of traffic flow and lane(s) observed. Each one-page form includes space to record information on 25 vehicles, the driver of that vehicle, and the outboard, front seat passenger, if any. When more than 25 observations were made at a site, additional sheets were used and all sheets for the observation site-period were fastened together. Observations included person gender, age category, and race in addition to belt use. When qualified passengers (outboard front seat, all except children in child restraint seats) were present, data was recorded even if "Unknown"; passenger fields in the data form are left blank only if no qualified passenger is present.

If data could not be collected at a site due to a temporary problem such as bad weather or a very temporary traffic impediment, collection would have been rescheduled at the same site for the same time of day and day of the week. In the case where a site could not be used due to a more permanent factor, the next available selected alternate in the same county-stratum was used. In future surveys, the original site will be considered if possible; otherwise, the alternate site will be selected as the new, official location.

Quality Control

Quality control monitors conducted random, unannounced visits to at least 10 observation sites for the purpose of quality control. The monitors ensured that the observer was in place and making observations during the observation period. Where possible, the monitors remained undetected by the observer. As noted above, PRG has had extensive experience in training seat belt use observers. All observers, whether or not new to the task, received training which includes both classroom instruction and field (road-side) practice.

Data was reviewed as received and no anomalies were found, suggesting the data do not reflect anything other than proper on-site seat belt use observations. Some cues to the contrary would include repeating patterns within the observation data, unusual proportions of vehicle type, driver or passenger sex, presence of passengers, seat belt use, excessive unknown seat belt use, or very high or low total numbers of observations. Some variation in these values is normal, of course. If any suspicious data patterns had been noted, PRG would have followed up to verify if observations were completed properly. Invalid data would be replaced in such cases. Again, no problems were detected and, thus, corrective actions were not necessary for these survey iterations.

Building a Data Set

Observation data were keypunched by Preusser Research Group, Inc. staff. A thorough check of the data revealed minimal errors, all of which were corrected pre-analysis. The data set was analyzed using the Statistical Package for the Social Sciences (SPSS) to generate non-weighted calculations. Microsoft Excel was used to determine weighted results, including estimation of the overall statewide average.

Seat Belt Usage Rate and Variability Calculations

Calculation of Overall Seat Belt Usage Rate

Seat belt use rates were calculated using formulas based on the proportion of the State's total DVMT "represented" by the site. Seat belt use rate calculations followed a three-step process.

First, estimated rates were calculated for each of the five road type strata within each county.

The general formula for combining observed belt use rates from observation sites on individual segments, for a single county-stratum, is shown in Formula 1. It is used when the county-stratum contains certainty segments. The contribution of each segment to the overall county-stratum rate is proportional to the "size" of the segment's contribution to the entire county-stratum traffic, i.e., its DVMT, adjusted by the inverse of the probability of the segment's being selected into the sample:

$$p_{ij} = \frac{\sum_{k} DVMT_{ijk}W_{ijk}p_{ijk}}{\sum_{k} DVMT_{ijk}W_{ijk}}$$
(1)

where $DVMT_{ijk} = DVMT$ for segment k in county-stratum ij; $p_{ijk} =$ the observed seat belt use rate at site $ijk = B_{ijk}/O_{ijk}$, where $B_{ijk} =$ total number of belted occupants (drivers and outboard front-seat passengers) observed at the site and $O_{ijk} =$ total number of occupants with known belt use observed at the site; and $W_{ijk} =$ the inverse of the probability of segment k's selection, as described in Appendix C:

(certainty segments)
$$W_{ijk} = 1.00$$
 or (random segments) $W_{ijk} = \frac{\sum_{l=1}^{N} DVMT_{ijl}}{n*DVMT_{ijk}}$

where N = total number of segments in county-stratum ij excluding the certainty segments and n = number of segments to be randomly selected including spares and oversampling.

In the case where there are no certainty segments in the county-stratum, as shown in Appendix B, formula (1) reduces to the simple Formula 1a:

$$p_{ij} = \sum_{k=1}^{n_{ij}} p_{ijk} / n_{ij} \tag{1a}$$

where i = stratum, j = county, k = site within stratum and county, $n_{ij} = \text{number}$ of sites within the stratum-county, and $p_{ijk} = \text{the observed seat belt use rate at site } ijk = B_{ijk}/O_{ijk}$, where $B_{ijk} = \text{total}$ number of belted occupants (drivers and outboard front-seat passengers) observed at the site, and $O_{ijk} = \text{total}$ number of occupants with known belt use observed at the site.

Next, stratum-county seat belt use rates will be combined across strata within counties, weighted by the stratum's relative contribution to total county DVMT, to yield a county-by-county seat belt use rate p_j :

$$p_{j} = \frac{\sum_{i} DVMT_{ij} p_{ij}}{\sum_{i} DVMT_{ij}}$$
 (2)

where $i = \text{stratum}, j = \text{county}, DVMT_{ij} = \text{DVMT of all roads in stratum } i \text{ in county } j \text{ from Table PubVMT2010, and } p_{ij} = \text{seat belt use rate for stratum } i \text{ in county } j.$

Finally, rates from the 15 counties will be combined by weighting them by their Statewide DVMT values $DVMT_j$ times W_j :

$$p = \frac{\sum_{j} DVMT_{j}W_{j}p_{j}}{\sum_{j} DVMT_{j}W_{j}}$$
(3)

where $DVMT_j$ = total DVMT for county j from Table PubVMT2010 and W_j = the inverse of the probability of their selection, as described above:

(6 counties)
$$W_j = 1.00$$
 or (9 counties) $W_j = \frac{\sum_{l=1}^{29} DVMT_l}{9*DVMT_i}$

The result will be a weighted combination of the individual site seat belt use rates.

Estimates of subgroups of occupants, such as male drivers, female passengers, male drivers of pickup trucks, etc., which are of particular interest to the State, can be calculated the same way.

Calculation of the Standard Error of the Overall Seat Belt Use Rate
Standard error of estimate values were estimated through a jackknife approach, based on the general formula:

$$\hat{\sigma}_{\hat{p}} = \left[\frac{n-1}{n} \sum_{i=1}^{n} (\hat{p}_i - \hat{p})^2\right]^{1/2} \tag{4}$$

where $\hat{\sigma}_{\hat{p}}$ = standard deviation (standard error) of the estimated Statewide seat belt use proportion \hat{p} (equivalent to p in the notation of formulas 1-3), n = the number of sites, i.e., 165, and \hat{p}_{i} = the estimated Statewide belt use proportion with site i excluded from the calculation. The 95% confidence interval, i.e., $\hat{p} \pm 1.96\hat{\sigma}_{\hat{p}}$, was also calculated. These values are reported along with the overall Statewide seat belt use rate.

Calculation and Reporting of Rates

As previously mentioned, an Excel spreadsheet was developed in which raw data observations were recorded and belt use and variability calculations were performed. Calculation of seat belt usage rates follow the formulas provided above. For the Statewide belt use figure to be reported to NHTSA, all observations were included, i.e., all vehicle types, drivers, and outboard front seat passengers. For the State's own use, seat belt usage rates also were calculated for subsets of interest, e.g., drivers alone, passengers alone, drivers and/or passengers within vehicle type, or males or females alone. The same calculations performed for the overall rate can be done for subsets of interest, substituting for the site p_{ijk} the site-subset p_{ijk} . However, further breakdowns of belt use warranted non-weighted number calculations, as weighting particular levels of subgroups decreases the reliability of the results.

June 2014 Florida Statewide Use Rate Survey Results

Observers recorded belt use information on 31,687 drivers and 7,138 outboard front seat passengers across 165 sample sites within 15 counties. Table 1 displays number of drivers and passengers observed per county, and in addition, separates the counties by region.

Table 1. Number of Observed Front Seat Occupants per County/Region

	Drivers	Passengers	Total
North Region	10,147	2,362	12,509
Alachua County	1,922	489	2,411
Duval County	2,632	521	3,153
Escambia County	1,792	414	2,206
St. Johns County	2,417	707	3,124
Volusia County	1,384	231	1,615
Central Region	10,426	2,255	12,681
Hillsborough County	2,231	441	2,672
Lake County	1,568	257	1,825
Orange County	2,268	486	2,754
Pasco County	1,952	576	2,528
Seminole County	2,407	495	2,902
South Region	11,114	2,521	13,635
Broward County	3,060	710_	3,770
Collier County	2,012	453	2,465
Lee County	2,401	650	3,051
Miami-Dade County	1,761	373	2,134
Palm Beach County	1,880	335	2,215
Statewide Total	31,687	7,138	38,825

The overall belt use rate for drivers and passengers combined measured 88.8 percent in June 2014 (Standard Error = 0.706%; 95 Percent Confidence Interval 87.4% - 90.2%). This rate represents Florida's highest use level to date.

Figure 1, on the subsequent page, shows the trend in belt use over time.

Surveys of belt use conducted during the 1990s indicated no sustained increase in Florida's statewide use rate. Florida's seat belt use rate then improved over time after the year 2000. Increases measured over this time are due, at least in part, to the implementation of highly and widely visible efforts to enforce Florida's adult seat belt law. A substantial rate increase was measured after implementation of the Primary law (June 30, 2009), and the rate has increased each year until the 2012 measurement, when the survey was redesigned in compliance with new NHTSA guidelines. Since then, Florida's use level remained statistically the same until the 2014 increase.

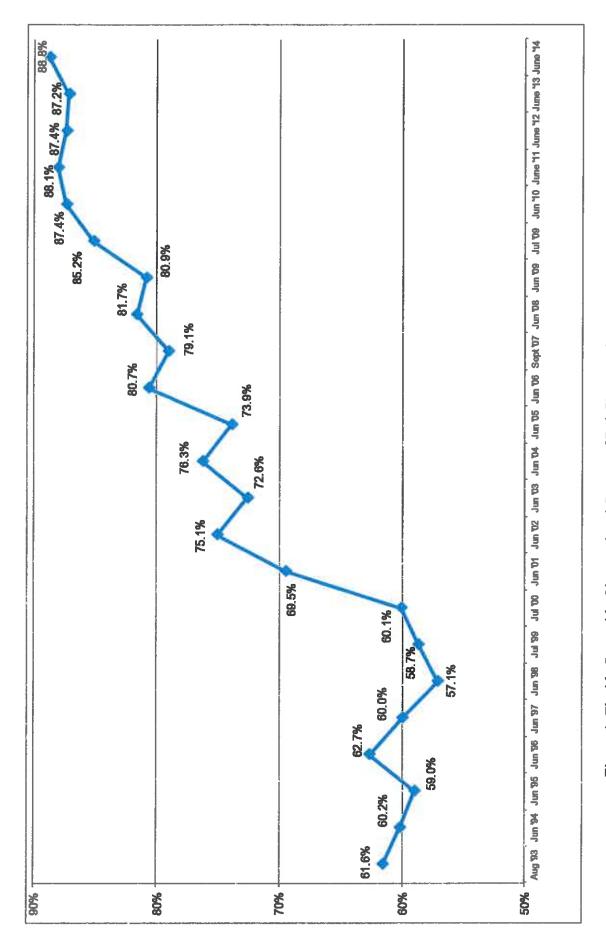

Figure 1. Florida Statewide Observational Survey of Belt Use Results; 1993 - June 2014

Descriptive Information - Based on Weighted Calculations

Belt use differed by roadway type. Figure 2 shows that belt use measured highest on Minor Arterials (92.1 percent) followed by Principal Arterials (90.6 percent) and Interstates (90.4 percent), all of which typically yield higher traffic densities with higher rates of speed. Observers measured the lowest belt usage on Local Roads (83.8 percent), which are less frequently travelled roadways, and usually found within neighborhoods in city limits. With the introduction of the Local Road functional class as part of the recently updated survey guidelines (2012), lower use rates and higher variability were expected.

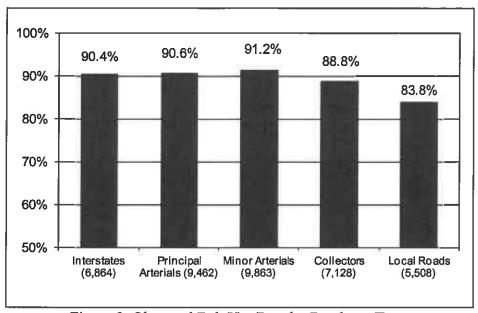

Figure 2. Observed Belt Use Rate by Roadway Type

The survey results indicated that belt usage measured lower among male occupants compared to female occupants by a 5.8 point differential (Figure 3). Furthermore, male passengers were less likely belted compared to male drivers (Figure 4). Male passengers measured 3.6 points lower than their driver counterparts (83.0 percent vs. 86.6 percent, respectively). Alternately, female passengers yielded a slightly higher rate (92.6 percent) than the female drivers (91.9 percent). These results are consistent with previous measures.

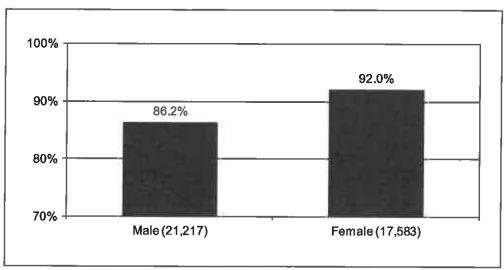

Figure 3. Observed Seat Belt Use Rate by Gender

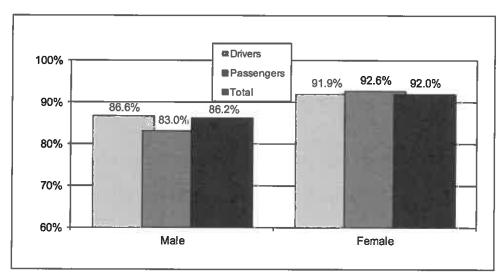

Figure 4. Observed Seat Belt Use Rate by Gender and Front Seat Position

Results from the survey indicated lower belt use among occupants in pickup trucks (79.6 percent) when compared to other vehicle types (Figure 5). Front seat occupants in passenger cars were most likely to be belted (90.5 percent), followed closely by occupants in sport utility vehicles (89.6 percent) and vans (89.2 percent).

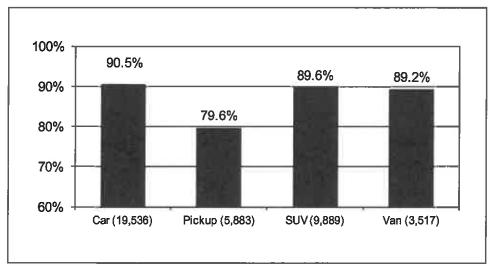

Figure 5. Observed Seat Belt Use Rate by Vehicle Type

Figure 6 shows the breakdown of male and female belt use within vehicle type. Occupants in pickup trucks were overwhelmingly male (84.7 percent) vs. other vehicle types. As previously indicated, male occupants were less likely to be observed wearing a seat belt and this appears to be the case regardless of vehicle type.

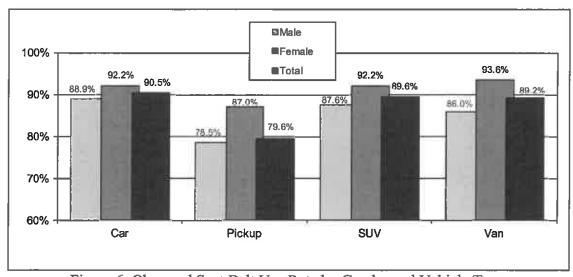

Figure 6. Observed Seat Belt Use Rate by Gender and Vehicle Type

Further evidence of the low use rate in pickup trucks can be seen below where vehicle use rates are examined by occupant type. The trend of slightly higher passenger use did not extend to pickups or passenger cars (Figure 7). Passengers in pickups were observed wearing seat belts the least often out of all occupant categories (75.6 percent).

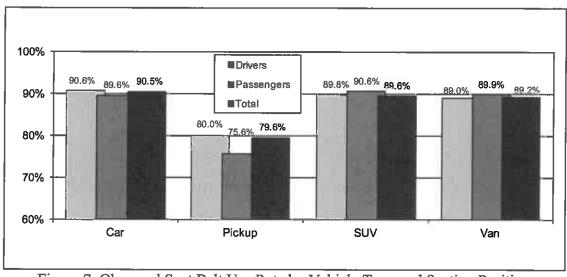

Figure 7. Observed Seat Belt Use Rate by Vehicle Type and Seating Position

Regional Information – Additional Weighted Results

The graphs that follow represent regional findings and are also based on weighted calculations. Figure 8 shows total occupant belt use by county, grouped by region. The county use rates presented here, although weighted, should be interpreted with caution. The survey design was not intended to provide official county belt use rates but rather a single, statewide use rate. However, further breakdowns suggest considerably lower local road belt use greatly contributed to the lower county rates. Figure 9 summarizes belt use by region, showing the highest overall use rate in the North area.

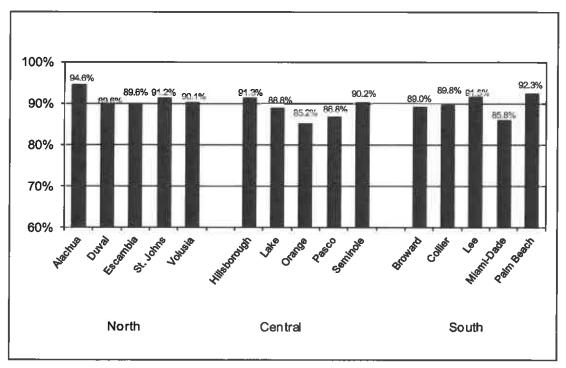

Figure 8. Observed Seat Belt Use Rate by County and Region

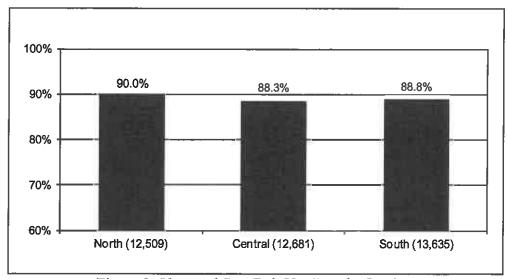

Figure 9. Observed Seat Belt Use Rate by Region

Figure 10 shows the consistency on a regional level in lower belt use of males compared to that of females.

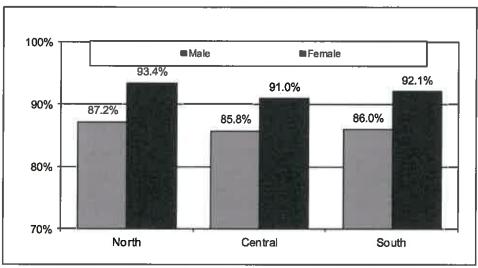

Figure 10. Observed Belt Use Rate by Gender of Occupant and Region

The statewide survey also found a consistent pattern of lower observed belt use among occupants in pickup trucks, regardless of region (Figure 11). Belt use among occupants in pickup trucks was at least 9.6 percentage points lower than the next lowest vehicle type measurement in each of the three regions, with a 10.2 point differentials in the North and South regions.

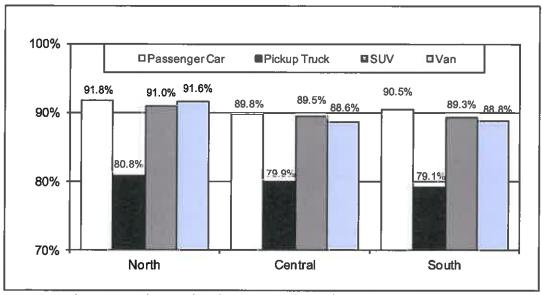

Figure 11. Observed Belt Use Rate by Vehicle Type and Region

Pre vs. Post CIOT 2014 Results

PRG conducted a Baseline statewide survey prior to CIOT in April/May 2014. Results from this survey and the post-CIOT survey in June 2014 were compared to estimate the effects of the CIOT program in Florida. Table 2 displays weighted use rates results of each survey. The premobilization weighted result is statistically significantly lower (p < .05; 1.5 percentage points) than the June weighted rate. Breakdowns of the weighted rates show that both driver and passenger use rates increase following CIOT. Table 3 provides further information on occupant characteristics based on raw, non-weighted data counts.

Table 2. Weighted Seat Belt Use Rates Pre-Post CIOT 2014

Weighted	Pre-CIOT April/	May 2014	Post-CIOT Ju	ne 2014	Pre to Post

Non-Weighted	Percent Use N		Percent Use	N	Difference
Sex					İ
Male	85.9	21,113	88.1	21,217	+2.2
Female	91.8	18,761	93.6	17,583	+2.8
Occupant Age				İ	·
16-59	86.9	31,039	90.0	30,320	+3.1
60 or older	92.0	8,113	92.9	7,637	+0.9
Under 16	91.6	750	94.6	755	+3.0
Race/Ethnicity					
White	89.6	28,055	91.5	27,234	+1.9
Black	83.9	4,553	85.8	4,841	+1.9
Hispanic	87.1	6,258	89.4	5,614	+1.7
Other	93.0	982	96.3	1,051	+3.3
Race (Males Only)				Ì	
White	86.8	14,724	89.1	14,726	+2.3
Black	80.6	2,331	83.0	2,566	+2.4
Hispanic	84.2	3,553	86.6	3,355	+2.4
Other	92.8	488	95.6	526	+2.8
Vehicle Type					
Car	89.9	20,074	92.2	19,536	+2.3
Truck	79.4	5,788	81.7	5,883	+2.3
SUV	90.5	10,259	92.5	9,889	+2.0
Van	90.5	3,791	91.3	3,517	+0.8

Although all genders, ages, and races/ethnicities showed improvements pre to post CIOT, the largest increase in belt use was among occupants of "other" – as in not White, Black or Hispanic – races (3.3 percent). Perhaps the most notable increases were those among younger occupants; those under 16 (3.1 percent), but especially those aged 16-59 given the fact that such a large group (nearly 20,000 occupants) increased 3.0 percentage points. Even with increases across all occupant characteristics, the differentials within the subgroups remained.

An examination of occupant belt use by vehicle type also showed increases pre to post-CIOT among all categories, with occupants in pickup trucks and passenger cars demonstrating the greatest rise in belt use (2.3 percent). The use rate increase among car occupants is notable, again due to the large representation of that vehicle type in the sample. Increases notwithstanding, occupant belt use rates in pickup trucks continue to lag behind the use rates of occupants in other vehicle types.

The non-weighted data presented in Table 4 concern location and daily travel characteristics. Most individual raw rates indicate higher belt use post-mobilization. Overall regional raw rates increased to over 90 percent belt use in June 2014. Not only is this the first time any region has ever measured at that raw level, all three regions managed to surpass it. Further breakdowns show there to be two relatively static counties pre to post (Pasco and Palm Beach), with increases in belt use found in 10 of the 15 counties observed (ranging from 0.6 to 5.7 percentage point increases). All but three counties (Orange, Pasco, and Seminole) increased from their June 2013 raw levels. However, two of those yielded a pre-post increase in 2014.

Increases in belt use were measured on all road types, with the highest point increase among local roads, followed closely by interstate roadways. Four of the five roadway types measured raw belt use levels above 90 percent post-CIOT. Examining belt use by day of week showed improvement on all days of week with Sunday, Monday, and Tuesday (the days after CIOT enforcement usually ends) exhibiting the highest change in use rate. Belt use by time of day was also examined, and while we measured a pre-post increases across all time periods (and slightly higher levels in belt use during morning and afternoon rush), there is little variance in the use levels throughout the day. In summary, the 2014 CIOT effort achieved its goal in improving seat belt use under the existent primary law environment, resulting in increasing Florida's use rate pre-post mobilization. Improvements were assessed across most of the characteristics in the data.

Conclusion

Florida's statewide use rate measured in June 2014 was 88.8 percent, the highest level to date. Both the April 2014 and the June 2013 result (87.3 percent and 87.2 percent, respectively) are significantly lower by statistical comparison. Local Roads, first introduced to the survey in 2012, had a much lower belt use rate than the larger, busier road type categories – just as before. Looking only at the other four strata, statewide belt use would have been 90.2 percent in 2014, which would have been significantly higher than the last measure without Local roadways (June 2011), 88.1 percent, the previous high point. Also worthy of mention is that the statewide seat belt use rate for Florida continues to be above the national average, as it has been for the last six years.

Statewide surveys conducted before and after the 2014 CIOT found that the program positively affected seat belt usage in Florida. The increases measured in 2014 were found in all regions, in both urban and rural areas, and across different occupant and vehicle characteristics, regardless of baseline use rate level. Statewide seatbelt surveys completed in 2014 show that the continued use of high visibility programs focused on seat belt enforcement can still increase daytime seat belt usage among all occupant types.

Appendix B. Survey Design and Sampling Plan Information

Overall Survey Design

The overall design was developed in four steps:

- 1. Counties for observations were selected from the 35 counties with the most passenger vehicle occupant fatalities and which total more than 85 percent of the State's total passenger vehicle occupant fatalities. Fifteen of the 35 counties were selected, with probabilities generally proportional to their DVMT.
- 2. Roads were stratified by combining related functional use classes within each county, resulting in five strata. Two sites per stratum were allocated in each county for the busier road types, three sites for local roads in each county.
- 3. Specific road segments were selected, within stratum within county, by randomly selecting from all segments with probabilities proportional to their DVMT.
- 4. Belt use estimation procedures and computations were developed reflecting the design and NHTSA reliability requirements.

County Selection

Table B-1 lists the 35 Florida counties with the greatest numbers of passenger vehicle occupant fatalities in 2005-2009. These 35 counties account for 85.4 percent of the State's total passenger vehicle occupant fatalities.³ The table also includes total DVMT tallies, derived from table PubVMT2010⁴, a tally of mileage and DVMT figures by Florida roadway type and county. These DVMT figures cover all roadways in the State. These 35 counties account for 89.8 percent of all DVMT. Fatality and DVMT figures for the other 32 counties are given in Appendix A.

We sampled 15 counties for this design, a figure consistent with recommendations in NHTSA's 1998 seat belt use measurement requirements and 20% greater than the 12 counties in the previous design. Sampling was probabilistic, based on total county DVMT.

The sample of the 15 counties selected is highlighted in Table B-1 and in Figure B-1. The selection procedure involved simultaneous random selection with the odds of selection proportional to the county's total DVMT. Selection probabilities for those 15 counties, explained in detail below, are shown in Table B-1.

 $^{^{1}}$ 2010 DVMT figures from PUB2010VMT, the annual State report to FHWA; includes all Florida roadways

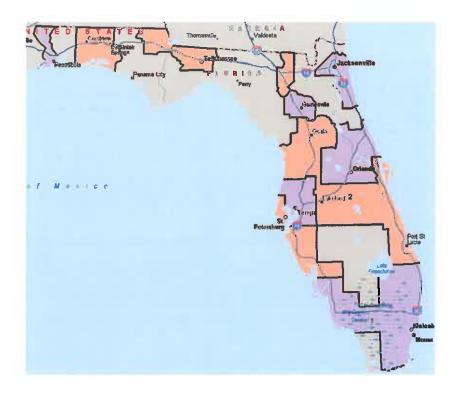

Figure B-1. Florida counties for sampling: purple = selected, peach = unselected, gray = excluded counties with less than 15% of all fatalities, 2005 - 2009.

The first step involved identifying counties which, by virtue of high proportions of total DVMT, would certainly be selected by the PPS procedure, and including them in the sample. DVMT percentages ("p") for the 35 counties were calculated, from 11.1% (of the top-35 county total) for Miami-Dade through 0.5% for Jackson. The percentages were multiplied by the total number of counties ("n") to be selected, 15. Five counties had n*p greater than 1.0 and were deemed selected with certainty: Miami-Dade, Broward, Palm Beach, Hillsborough, and Orange. These counties were set aside, and DVMT percentages for the remaining 30 counties were calculated. These values were multiplied by n = 10, the number of counties remaining to be selected. One county, Duval, had n*p greater than 1.0 and also was deemed selected with certainty.

The remaining 29 counties had their DVMT percentages recalculated and multiplied by 9, the number remaining to be selected. No additional counties had $n*p \ge 1.0$. The counties were randomly ordered, to eliminate sequential dependencies and cumulative values of the DVMT percentages*9 were computed.

A random number from a rectangular distribution between 0 and 1.0 was drawn, and 9 counties were selected: the first county whose cumulative DVMT percentage*9 was equal to or greater than the random number, the first whose cumulative DVMT percentage*9 was equal to or greater than the (random number+1), ..., and the first whose cumulative DVMT percentage*9 was equal to or greater than the (random number+8). This produced a sample of 15 counties. Six had probability (selection) = 1.0; the remaining had probability (selection) = 9 times their DVMT

proportion of the DVMT of the final group of 29 counties. Those selection probabilities are shown in Table B-1.

Road Segment Sampling Plan Development

The next step was to determine the distribution of the number of observation sites across counties. In the previous plan, road functional classes are combined into four strata: Interstates and Other Expressways, Other Principal Arterials, Minor Arterials, and Collectors. We retained these strata and add a fifth stratum for Local Roads.

We distributed sites equally across counties and by strata within counties except for Local Roads. Our number of sites per stratum within counties is three for Local Roads and two for all other strata. This provides coverage for the four strata in the previous design, and is generally comparable, but provides somewhat greater emphasis for Local Roads, where one may expect fewer observations per observation period and thus larger error variance for the individual sites.

The State of Florida provided multiple databases of road segments, a Statewide database with all roadways that are Collectors or larger, plus a small number of local road segments, and separate TeleAtlas databases for each of the 15 selected counties that include all Local Roads. We drew segment samples for Collectors and larger from the Statewide database, for Local Roads from the separate county local road databases.

The Statewide road segment database includes more than 34 thousand linear miles of roads with total DVMT of more than 424 million vehicle miles traveled. The Statewide database is essentially a complete census of all roads other than local roads, as confirmed by comparing the road segment database to the PubVMT2010 table⁵. The Statewide database includes about 98 percent of Interstates and Other Expressways, 99 percent of Other Principal Arterials, 99 percent of Minor Arterials, and 96 percent of Collectors, based on mileage traveled. DVMT from the PubVMT2010 table for these roadway categories is more than 419 million miles; from the Statewide database, it is 416 million miles, or more than 99 percent. Part of any discrepancies may be due to recording differences between two separate databases. It is reasonable to consider the Statewide road segment database as an exhaustive listing of all except local roads.

By contrast, the Statewide database includes just 3,355 miles of local roads and 4.9 million DVMT, compared to over 92,000 miles and 117 million DVMT in PubVMT2010, about 4 percent of each. As an alternative source of local road segments, the State provided separate databases (TeleAtlas, version 10.2) for each selected county. The county databases include all Local Road segments in the county; we used those databases to draw samples of Local Roads.

Of the road segments listed in the Statewide database, 10,488 road segments with total length of 12,181 miles and 257 million DVMT (excluding local roadways) lie within the sampled counties. The road segments in the sample counties are shown by county in Table 2.

⁵ The annual VMT report from the State to FHWA. It includes mileage and VMT broken down by county and by roadway functional classification within county.

¹ In Florida Statewide Road Segment Database; excludes Local Roads

Also shown in Table 2 are Region assignments for the 15 counties. In past belt use reports, Florida was divided into North, Central, and South Regions for reporting purposes, and we will continue that activity. The "region" designations are informal; region has not been considered in the selection of sample counties.

The distribution of road segments in the Statewide database across the 10 largest road functional use classifications, excluding Rural Local and Urban Local, in the 15 sample counties is shown in Table 3. Some of these road segment categories are quite small. In order to produce categories which have significant numbers while still retaining meaningful distinctions, we collapsed the road segment categories into four strata: Interstates and Other Expressways (n = 592), Other Principal Arterials (other than interstates/expressways) (n = 2,345), Minor Arterials (n = 2,734), and Collectors (n = 4,777). This categorization is the same as used in previous Florida reports.

¹ From Florida Statewide database; Local Roads are excluded

DVMT figures are available for all of the road segments in the Florida Statewide database and in the 15 TeleAtlas local road databases. Table 4 presents the distribution of road strata across counties and shows for each the number of segments and the sum of segment DVMTs. In Table 4, the values for Local Roads are based on all road segments listed in the TeleAtlas individual-county databases, and all other values are from the Statewide database.

Adequate numbers of road segments within each county-road type stratum support the targeted sample size, with one exception. Lake County has just one listed expressway, a short segment of the Florida Turnpike. We used that segment as the required two segments, coding belt use in one direction and, separately at a different time of day and day of week, coding belt use in the other direction.

Table 4. Roadway Functional Strata by County, Road Segments and DVMT

¹ Based on all valid local road segments in the 15 individual-county databases

Appendix C. Seat Belt Observation Instructions

These instructions describe procedures for observing seat belts. Please keep these instructions handy for quick review.

1. Observation Sites

Our Statewide sample of randomly selected controlled roads and freeway exits includes 165 observation sites across 15 counties.

This is the first time that this specific design and list of observation sites has been used. You may be the first person to actually visit the sites. If so, it will be up to you to find a suitable location for observation or, if the road segment is in some way compromised (e.g., closed or under construction) so that normal traffic can't occur, disqualify the site and move to the next alternate.

You will be given a general map of the road segment on which you are to observe (together with time for observation and direction of traffic to observe). When you get to the general location, your first task is to find a specific location for observing. We will provide a recommended location for observation; however, should it be unsuitable, you can select a different location along the road anywhere between the road segment's end points. The general map will show the end points of the road segment, or identify possible highway exit ramps, on which observations can be made.

It is recommended that you first look for a place where traffic must slow naturally, for a traffic control (stop signs are better than traffic signals) or a sharp curve on an expressway exit ramp.

Select a spot where you can observe safely, without risk to yourself or to traffic (e.g., by being a distraction or by impeding their view), and where you can readily observe drivers and outboard front seat passengers. Note that the direction of travel you must observe has already been specified.

When you have selected the exact location for observing, show the location on your general map and then make a detailed "site map" – a drawing that shows where to stand, the traffic flow you're observing, the names of the intersecting roadways, nearby buildings, etc.

2. Observation Days and Times

You will receive a schedule that has assigned observation locations with day of week and time of day. You must adhere to this schedule if at all possible. Observe in poor weather as long as you can stay dry (enough) and your ability to make accurate judgments is not compromised.

Each day is comprised of three-to-six daylight time periods, and your schedule will include three to six locations to observe. The time periods are:

3 Periods	4 Periods	5 Periods	6 Periods
7:00 – 10:30 a.m.	7:00 – 9:30 a.m.	7:00 – 9:00 a.m.	7:00 – 8:45 a.m.
10:30 a.m. – 2:30 p.m.	9:30 a.m. – 12:00 noon	9:00 – 11:00 a.m.	8:45 – 10:30 a.m.
2:30 – 6:00 p.m.	12:00 a.m. –3:30 p.m.	11:00 a.m. – 2:00 p.m.	10:30 a.m. – 12:15 p.m.
	3:30-6:00 p.m.	2:00 – 4:00 p.m.	12:15 – 2:30 p.m.
		4:00 – 6:00 p.m.	2:30 – 4:15 p.m.
		<u> </u>	4:15 – 6:00 p.m.

You need to observe for one full hour at each site. The observation hour should be continuous and should fall entirely within the observation period. Use the extra time in the observation periods to move between sites, locate and document your observation positions, eat lunch, etc.

3. List of Sites

In your packet of materials is your list of observation sites, together with maps, descriptive information (road names, cross streets, direction of travel to observe, etc.), and schedule.

4. What to Do if a Site Is Unusable/Inaccessible

Alternate sites with the same information are also provided. If you determine that the primary site cannot be used, you must select an alternate site. The alternate MUST be:

- The first site in your set of alternates that "matches," i.e.:
 - o In the same county.
 - Of the same Roadway Type (there are 5 types; in decreasing size and traffic volume, they are: Interstate/Expressway, Other Principal Arterial, Minor Arterial, Collector, and Local).

If you must move to an alternate site, indicate on the general map for the primary site why you can't use it, go to the alternate, pick an appropriate observation spot, document it, etc.

If you use an alternate site, you must observe at the site during the same time period and day of week as the schedule for the site it replaces.

5. Which Roadway and Direction to Observe

It is important to recognize that one can<u>not</u> simply choose to observe traffic on either of the intersecting roadways at an intersection. The roadway and direction to observe are clearly indicated on the general site map. If possible, you **must** observe traffic on this roadway traveling in the direction indicated. If the roadway is a freeway/expressway/interstate, you are to code motorists who were traveling in the direction indicated as they leave this roadway via an exit.

If you cannot observe belt use for the direction specified, you may switch and observe traffic in the opposite direction. Switching direction is a last resort. Do this only if there is no safe place

for you to position yourself or observations aren't possible due to something like sun glare; if you do this you must document the reasons for switching.

6. Which Vehicles to Observe

- a. Code passenger cars, vans, jeeps, pickup trucks, and sport utility vehicles (SUVs) that are less than 10,000 lbs GVWR. Within these categories, there are no exceptions; code commercial vehicles (any vehicle with a sign on the outside), government vehicles, emergency vehicles, etc. Do NOT code large buses and heavy trucks.
- b. You will have selected an observation point where you expect you will be able to code nearly every qualified vehicle. If traffic is moderate and you are near a stop-sign-controlled intersection (or a roundabout, or some other location where all traffic is slowed), this is realistic. If you are near a signal-controlled intersection, you may find that free-flowing traffic on the green signal is moving too fast. In that case, go to step (c). The goal is to have very, very few "unsure".
- c. If you need to observe traffic stopped/slowed by a red light, begin observations with the **second** vehicle in a line of vehicles stopped at the traffic signal. Code restraint use by occupants of the second vehicle, then code the third vehicle in line, etc. Continue until the vehicles begin to move too rapidly with the green signal.
- d. On surface streets with multiple approaching lanes of traffic, code traffic in all approaching lanes **including** ones for right or left turns, if any. At signal-controlled intersections, begin with the <u>second</u> vehicle in the near lane, then the second in the next lane, etc., to the third in the near lane, etc. For the next red signal, begin with second vehicle in the lane you left off at on the preceding signal phase. If the level of traffic is too high to code all lanes, observe each lane exclusively for an equal length of time, broken into 10 or 15 minute periods (with each lane observed for the same number of periods).
- e. In the case of freeway exits, find a location controlled by a sharp turn, a stop sign, or a traffic signal so that you can observe nearly all vehicles as they slow down. If possible, do not choose a location that depends on vehicles slowing because they can't merge smoothly, since that would bias your selection to that category of drivers.

7. Heavy Traffic Conditions

Heavy traffic conditions should not affect observations at signalized intersections. For example, at a red light, you should begin with the <u>second</u> vehicle in the near lane and code the occupant and vehicle characteristics. You should then proceed to the second vehicle in the next lane, etc., then the third vehicle in the near through lane, and so on until traffic begins to move (you can walk alongside the line of vehicles). It is likely that, in heavy traffic conditions, there will be more cars stopped than you can code before traffic begins to move.

At freeway exits, it is possible that, in heavy traffic conditions, there is an "unending" line of vehicles slowing/stopping before entering the flow of traffic. In this situation, begin with the second vehicle in line (vehicle "A"). Code the pertinent information for vehicle "A" and mark it on the coding sheet. One or more cars may have passed while you are completing the coding for vehicle "A". At the moment coding for vehicle "A" is complete, look up and identify the next slowed/stopped vehicle. Do **not** code that vehicle, but code the one <u>behind</u> it. Continue in this fashion throughout the coding period for that observation site.

8. How Long to Observe

Observe at each location for a full 60 minutes. A fixed observation period translates to high volume roadways contributing more observation data than low volume roadways. That's the way the study is designed.

9. Whom to Observe

- a. **Front seat drivers and outboard passengers**. If there are more than two occupants in the front seat, only observe the driver and the passenger (regardless of age) closest to the passenger-side door. Thus, if there are three occupants in the front seat, the observer would ignore the middle occupant.
- b. Code everyone in the driver's seat and the outboard passenger seat except children in child safety seats. Do include all other children including children in booster seats. Leave fields for passenger data blank only if there is no qualified passenger present.

10. Recording Data

- a. Each coding sheet contains room for 35 vehicles.
- b. At the top of each coding sheet is a place for indicating the site code, site name (street/road/highway and identifier such as cross street or exit number), date, day of week, weather, and time of day. At the bottom of the sheet is a place to indicate page number and how many pages of site data there are. Make sure this is filled in accurately and completely for each coding sheet. For "location code", write in both the site number and the street/road location. THE LOCATION CODE IS EXTREMELY IMPORTANT.
- c. Please place the coding forms in order in envelopes to return to PRG-South. Keep all the coding sheets for a county in one envelope. Within a county, try to place the coding sheets in order from lowest to highest intersection number. For each intersection, place the pages in order (e.g., 1 of 6, 2 of 6, 3 of 6, etc.).

11. Codes

a. Vehicle: Indicate the type of vehicle in which the person is riding.

C = Car

V = Van, minivan or other like vehicle

T = Truck, i.e., pickup truck with a separate bed, even if enclosed

S = Sport Utility Vehicle

- b. <u>Sex</u>(S): Note the gender of the person being observed, male (M) or female (F) or unsure (U).
- c. Age (A): Note the age range of the person being observed.

C = Child age 15 or younger (passenger only)

Y = 16-59

O = 60 years or older

U = Unsure

d. Race: (R) Note the race of the person being observed.

W = White

B = Black

H = Hispanic

O = Other

U = Unsure

e. Restraint Use

<u>Seat belts</u>: Code if the occupant is (Y) or is not (N) wearing a seat belt. **Code based on the shoulder belt.** If the shoulder belt is visible and properly positioned, code Y. If the person is adequately visible and no shoulder belt use is seen, code N. If you cannot see the person clearly enough to determine whether or not a shoulder belt is visible, code U (uncertain). In general, try to avoid the U code.

If the shoulder belt is improperly fastened, i.e., looped behind the back or under the arm, code N for improper use.

12. Returning Materials After Completing Observations

Make sure to return all materials back to PRG-South:

- a. Completed coding forms
- b. Unused coding forms (only after the <u>last</u> survey)
- c. Site maps (with any changes noted only after the <u>last</u> survey)
- d. Maps (with any changes noted only after the last survey)
- e. List of intersections (with any changes noted only after the last survey)

13. General Tips

Conducting seat belt observations is not particularly hard work, but it is tedious work. Conditions are often hot and humid. Observers must make a special effort to maintain the quality of the observations. Here are some tips and recommendations based on years of conducting these observations.

- 1. Dress for the work. A hat, sunscreen and sunglasses are essential. If you don't have the complexion that will allow several hours in the sun, you should wear long pants and long-sleeved shirts. The discomfort that comes with the heat is much more bearable (and considerably shorter) than a severe sunburn.
- 2. Wear an orange safety vest at all times. Drivers are wary of people hanging around corners peering into cars, especially if they have kids in the car. The vest gives you an "official" air that may put drivers at ease. Still, don't be insulted by windows going up, doors locking, etc.
- 3. You will have an identification letter from DOT; keep it handy. Police officers and others will probably not be aware of the project. If anyone asks what is being done, tell them and show them the letter.
- 4. Be thoroughly familiar with all the procedures in this manual. Just one person consistently making the same mistakes can bias the results. The point of this research is to get an accurate reading of seat belt usage so education campaigns can be developed for low usage groups. Accurate information is of paramount importance.
- 5. Each observer is ultimately responsible for his/her work, as well as safety. Remember, observation requires that you stand close to traffic. Stay alert and be ready to react.
